John,

I have seen and used a small diameter telephone 30-40 foot pole mounted on the side of a 10 foot one. The 10 foot one was planted firmly in the ground and the top of the 10 foot had a pulley to the to the taller one. The taller one had it's base bolted to a base pivot point of the 10 foot. Easy to tilt up and lower with care. With the treated poles, life is >20 years. The taller one sometimes had the foot pegs.

Mel, K6KBE

i certainly did not mean to imply that these folks are any less deserving--
indeed, I wrote my Congress critter to encourage him to co-sponsor to
extend PRB-1 to CCRs and private restrictions--
http://www.arrl.org/news/house-bill-would-require-fcc-to-extend-prb-1-coverage-to-restrictive-covenants

any ham who has not done so, should write his or her congress critter
urging them to co-sponsor this bill--and most congress critters take
electronic submissions--

From: David V Colton
Topic: 33069 Message: 33318

Thank You Van!
All duly noted. I WILL watch what I "say" in print in the future. The FCC does not find the word I chose to describe said person as offensive...but YOU are the Moderator/Owner and what you say-go's. I was VERY incensed by the comment's, and with the recent loss of my father in a $5,200 a month facility that barely met his basic needs, coupled with this guy standing up for how we let rest homes treat our elderly...kind of drove me "crazy" to say the least.
Sadly, it's a fate we all will face someday. I spent my whole life taking care of people, in more ways than one. And now as my time approaches, the younger ones want to put us to the curb as garbage. Very Ironic.
Anyways, I will watch what I say, and HOW I say it in future post's.
73,
Dave-KJ4PF

Subject: Re: [ham-antennas] NEW Challenge Rest home [MODERATOR's TAKE]

I am the Moderator, 1 of 2
I am the Owner of this List, also 1 of 2

This is NOT political
This is NOT religious
This is Life in the U.S.A. I did not see anything that was not basiclytrue. I did see a LOT of opinions.

The man or corporation that owns a facility generally makes the rules,which cannot be unlawful,
but can be controversial.

These posts have been a classic example of (a little raw) ofunderstandings, misunderstandings.
and feelings on both sides. I spent 42 years in government, ownedrental property, spent military time, etc. I have come under folks laws and rulesevery day of those 42 years.

So, the postings have been a little rough, but folks, you may not likewhat you're hearing or the way it was written, but my only complaint is the word"a..h...", and the concepts of control
by an owner, state, local or federal entity (meaning the laws or ownersrights) was what was discussed.

However, bad language or offensive words, subjects mentioned on the rulesthat are posted once a month,
are my major concern. More of that will result inremoval/moderation at the least.

So I would watch the language, or sanctions will be applied.

Van Lincoln WD8AAM

Sorry about your dad. That makes it personal and a little hard to be cool.
And nothing else reminds one of the issues of advancing age than that of
of same sex parent. Especially, if they were, as my dad, is a young father.
He was 19 when I was born. Which makes me have different perspective
re him than he does with my siblings, who are 40 to 44, and my 24 y/o son
who was born when i was 34 re me.

Hi John,

Building a tower out of wood was more common in the past. If you are a subscriber to QST, do a search on for wooden antenna towers. Also, CQ magazine has been around a long time and access to the archives can be purchased. Again, do a search for wooden antenna towers.

Did the seaches myself about 5 years ago, out of curiousity. Sorry, didn't keep any of the materials I found as there was nothing built. Do remember they went from about 20 ft to 100ft height. Remember, the higher a tower goes, the bigger footprint it will need because of the guy wires.

Did you say something offensive? <<GRIN>>

Anyone remember George Carlin's, "Seven words we will never hear on TV"? Heard 'em all now.The FCC has said any word used in a 'performance' is acceptable. Years ago..in the early 70's, I was an FM announcer on KGLR-FM in Reno, Nevada. Once, when my midnight shift started, I played the entire Broadway production of HAIR, un-censored...it was acceptable even back then.I also played music from GROOTNA (A blues/jazz/soul fusion group) as well as the original Jefferson Starship album, BLOWS AGAINST THE EMPIRE, as well as the now famous Pink Floyd hit song, MONEY. All of which were laced with 1 or more of the 7 words Carlin spoke of. Heh.One always had to be careful playing any live cut with Gracie Slick singing...Miss foul mouth on stage! LOL!

I could see carefully designed and built wooden tower being such that it does not
offend the fashion police. Kind of like the OM who gets by with his antennas in
CCR restricted development because one supplies free WiFi to most of the development. If people like somehting they dont tend to bitch about it.

Wood is nice but steel is easier to work with and does not have to be replaced in a few years. I have a wood tilt over for my full size 40M vertical with a raised feed point and a steel tilt over for my beam. Today it supports my hex beam and a 160M delta loop.
http://s1102.photobucket.com/user/KD0ZZ/media/DSC00266.jpg.html

A rough sketch of the steel,

http://s1102.photobucket.com/user/KD0ZZ/media/TiltOverB.jpg.html

The wooden tilt took more drilling and work than the steel.

http://s1102.photobucket.com/user/KD0ZZ/media/Multi%20Band%20Vert/MBVert005_zps78008c01.jpg.html

The above it just my way of looking at it.

Hi Dave and THANK YOU for the note. I sincerely appreciate it!

I am 70, so I share and have a lot of feelings
for what you stated, as my time is coming.
I am looking forward (in some ways) to the
challenges of being old, but still involved with being
a 'HAM' and keeping my mind occupied while living
the rest of my life. One of my resources is
my ever-present computer. That alone can make my
final days interesting. One experience I had
was when I went to a FAA school in Oklahoma City
on the IBM 3083 mainframe system. I had to live there
for 6 months, and my only hands on learning came
during school hours. I did live in a short term lease
apartment, which didn't allow ham radio. This
gave me the chance to experiment. #1. my 2-meter HT gave me
access to the ham community, and short antenna
could be put into a drawer so the landlord couldn't find it.

#2. Next, HF (my FT-747GX 100watt) unit was a
little bigger problem. But I solved that also. I built a
15 meter dipole which I pinned to the wall at the
ceiling level. SWR was almost 1:1. Worked great. Then I
wanted 20 meter capability. I built two small
coils on a 5 inch pieces of 1" pvc, bought some hookup wire from
radio shack, hookup wire close wound on the pvc,
and alligator clipped them to the ends of the wall 15 meter
dipole. I had 1:1 SWR on 20, and worked all over
within about 500 mile radius with a very respectable signal.

My point is, I have no fear that I'll still be
playing ham radio in my old age, even in an assisted living
situation, but then again, a nursing home will be a different issue entirely.

So while I don't like to think about end of life
issues, I view my options with optimism. My parents are deceased,
and my in-laws also deceased. I am familiar with
stay at home, and dying in a home setting. Not pleasant,
but MUST be dealt with. I try to make the best of it.

Van Lincoln WD8AAM

p.s. and Dave, I do feel your pain.

==========

I tied to help an old (85) friend (Frank AA4UZ) in his assisted
living home (in his hometown) about 10 or 15 years ago. He sold his
personally (pride and joy) built HW-100 and bought an Icom IC-706, the
menu system got him lost every time and taping a 15 meter dipole up on
the wall resulted in setting off the fire alarm with every key down.
Running a coax out the window was my only suggestion.
I never heard how he made out with that, then he moved off.
--
Ron KA4INM - Youvan's corollary:
Every action results in unwanted side effects.

33330. Re: Connecting wire to insulator at the end of dipole

Yahoo group: ham-antennas (2014)

From: nm9p@...
Topic: 32985 Message: 33330

For me, it depends upon 1) What power level I am running, 2) What kind of wire I am using (size, stranded/solid, insulated/uninsulated) and 3) how much weight I am supporting.

I do not recommend soldering the ends because it reduces flexibility and weakens the wire.

I have put up many, many wire antennas with insulated wire, most recently a 160 Meter Offset Fed Dipole with #14 THNN and I simply bend the wire back on itself for about 3-4 inches and tie a sheet bend or modified sheet bend with nylon or kevlar rope. The knot, when under tension, clamps the wire against itself and won't let it slip. I have had this type of connection last for years and years without problems. I have done this with bare stranded copperweld as well with modified fishing knots that reduce the risk of the bare wire cutting the rope.

However, I only run 100 watts at present. If I were running high power, I would use a good insulator and either use the twist method or cable clamps to hold the wire ends.

My guess is that your overall performance will be better with most of the wire as high in the air as possible, even if you must give it a small bend. 45 degrees doesn't seem to be extreme. My own 160 Meter Offset Fed Dipole has the short leg straight and the long leg making TWO bends of about 80 and 45 degrees respectively into the shape of a C.

All antenna installations are compromises. But my general rule is that there is no substitute for altitude!

First of all I want to thank all of those who gave constructive suggestions. While some were not possible due to circumstances beyond control, others were good. I would like to offer a comment on rest/nursing homes and the regulations imposed on them. In one small section of California law that reads:

Right to self-determination and communication with and access to persons and services inside and outside the facility

Note the lack of definition or limitation that clause allows. Sounds like a good place to start with the provider. Will let you all know.

My Windom’s short side is straight and the long side has 2. 90 degree bends. My height above ground is 12 foot on one side, 17 feet on the other. Generally speaking, if I hear it, I talk to it…no matter where they are….I have talked all over the world with my configuration, 6 through 160.

I am planning to raise the wire up another 10-12 feet…I use 2x2 redwood heartwood ‘poles’ as supports, every 10 feet, bolted to a good neighbor fence. Don’t know is the 16 foot, 2x2 ‘poles’ will survive the 100 mph winds we oft host at my location…Guess we find out…I may have to run some guy wires on the upwind side of the of the supports to hold them steady. PCP pipe is too flexible to extend that high…AND… The wife would object to them as being unsightly. (I sorta agree with her on that one!)

BTW My Windom is coax fed…ladder line would not survive the winds up here. (Foothills above Reno, Nevada.)

I respect everyone's beliefs..And I rarely use any unacceptable words on the air..in person is another story.specially if I am frustrated with some government agency or business. My thought is simple..if a business wants my money, and I am unhappy enough to use some choice words, they will listen to me, like it or not.

Years ago, I was disputing an unknown charge on my furniture store credit statement. I used a few words to emphasize my frustration. The guy said he didn't have to listen to that kind of talk and hung up on me.

As I was buying a new house full of new furniture, guess who wasn't the beneficiary of my eventual $15,000.00 purchases. Being the spiteful individual that I am, I took the receipts of all the furniture and decorations I had purchased, went to the store where the guy who hung up on me worked at, and asked him (nicely) if he missed the $1500.00 or so, commission check he didn't receive because he was offended with my language. The store manager was present (at my request) so he knew the store lost a big sale.and as I got up to leave, I cut up their credit card and left it on the manager's desk. In front of me, (Which was wrong, in my book! He should have waited until I left, then called the salesman back in.) the manager asked the salesman to stay..I hope he got an earful from the boss..

I am sure you will disagree with me with some of my comments, but that is ok with me, I understand your sense of correctness! But, where I come from, putting money in the bank is far more important to my (AND my fmily) than my sense of morality. (As long as it is legal.)

Chuck, With respect to you and your belief's, if you were in my house, I would be careful to watch my 'tongue'...as I do when I am on the air..

The group I chat with every morning on 75 meters, is pretty good about language.the hate and discontent groups are not my bag, so shy away from them, as I do with religious groups. If the conversation, starts to get political, no matter my own belief's, I bid everyone adieu and go somewhere else.

Toodles! (Go ahead and laugh.I've been saying that for years!)

I love cats! I have two Bengals, and whenever a repairman comes to the house for something, Sophie has to be right there, supervising.. Our dishwasher croaked while still under warranty...as the repairman had everything apart to get at the problem, Sophie hopped right in to the washer and proceeded to tell the repairman exactly what to do. There was quite a conversation going on between the repairman and Sophie!

I video'd it with my phone, but screwed up and lost the video...(Very upset at myself....would have been a good YouTube video!)

BTW..I have always enjoyed you tilt-over tower..I forget what group I first saw it on...but though it was quite nifty...if I had the room for a fold-over, I would seriously consider your design.....a heck of a lot cheaper than a steel tower and not as 'ugly' (As my wife says!)

The tilt over system has it plus and minus. If you build very tall it gets heavy when you tilt, but it is easier to tilt than to climb a tower for a old man. I own my own land so I have to ask no one except the XYL when I build something. A bonus with retirement is room for the tilt over but had a few trees in the back yard were in the way for my 160M delta loop.

Steve wrote:

"I was referring to the Sinclair antenna, I was just venting about the J-Pole"

OK ... then the strange behavior was the flat SWR you saw on 440, right?

I expect that's happening because it is close to the 3rd harmonic, where a dipole comes into resonance again, and the SWR drops. 440 is a bit away from the 3rd harmonic on that antenna model (it should be around 490 MHz), so that is somewhat unexpected. And of course I am assuming that by "UHF" you mean the amateur 440 MHz band. Do you have a way to measure its SWR vs. frequency up there, over a wider range, say with an antenna analyzer?

Or maybe the antenna has some sort of absorbing bandpass filter (like a duplexer with dummy load) that makes it present a low SWR for anything sufficiently far out of band. Or it use really lossy coax. But that seems doubtful.

Regards,
Andy

Third harmonic would explain it. The cable is not too lossy, I put load & Bird at end and it seemed ok. The pattern must be interesting, but I have nothing in that frequency range in this area,

My FT897D doesn't give me a SWR warning so this will work on VHF, sort of, until I get a new antennas & tower, probably next spring when I get back from Virginia.

I would convert this to amateur but it needs different harness and larger dipoles. So I could keep the mast and mount. Some farmer will buy it from me, eventually.

I have built poles to 25' by using 2X lumber and sandwich a 2 X 4 between two 2 X 4 with a 2' overlap. I might try to build one taller with maybe 2 X 6 at the bottom. You can put a 2 X 6 or 2 X 8 in concrete with several feet above ground and use heavy bolts to secure the pole. Remove all bolts except one to hinge the pole up and down. Careful, it will be heavy. Have any of you done this and how high is practical with 2 X lumber?

You can use treated lumber for a long life span.

They around here have been using a LOT of laminated (Glued) wood power poles. A quick Google search shows one company with ones that go as high as 165 feet! and 165 feet dead end UNGUYED!!! where it has to hold back thousands of pounds of the wire tension!! WOW!!!

OK I like the 40 Ft Mine is a 33 Ft Crank up and easy to work on. How do you plan to mount antennas and work on it ?

You□re going to climb it? What are you going to do in 10 years paint it, it may have dry rot?

It may be unsafe in 10 years?

Hi ALL:
If this subject was covered in the past please give me direction to same regarding building a wooden tower to mount antennas by this group.

I am looking to build a wooden tower upon which to mount some antenna's. I would say the that it would be on the order of what you see in those old western flicks, of the little windmill H2O pump tower.

I am thinking a 40' structure would be acceptable or even 60' may be better.

Thank you!

33346. Balun 4 to 1 and 1 to 1 differance

Yahoo group: ham-antennas (2014)
Date: 2014-07-23 18:42:29 UTC
From: gatewood_bill@...
Topic: 33346 Message: 33346

What is the actual difference between a 4 to 1 and a 1 to 1 balun ? When do you use each one ? Thanks

33347. Re: [ham-antennas] Balun 4 to 1 and 1 to 1 differance

Yahoo group: ham-antennas (2014)

Topic: 33346 Message: 33347

"gatewood_bill" wrote:

"What is the actual difference between a 4 to 1 and a 1 to 1 balun ?"

The difference is the impedance transformation. The 4:1 transforms the impedance by a ratio of 4:1 (or 1:4 depending on which way it faces). Thus, it might be 50 ohms on one side and 200 ohms on the other. Or 300 ohms on one side and 75 on the other. Etc.

There might also be differences regarding voltage balun vs. current balun, or which end is unbalanced, etc., but those are incidentals not strictly related to which impedance ratio your balun has.

"When do you use each one ?"

You would use a 1:1 when you do not need an impedance transformation. For example, interfacing a dipole to a coax feedline.

You would use a 4:1 when you do want an impedance transformation. For example, interfacing a large loop or maybe a folded dipole to a coax feedline.

Regards,
Andy

The people in a small business are like a family to each other. They're all going to stick up for each other. Joe, let's say I want to use foul language to your family, how much do you generally charge for that right?

The best thing for the morale of a business is to fire the disgruntled and rude customers. There's 15,600 google links for "fire customers"; it's very well-known.

Turn your argument 100%. If you were nice to people you could have probably gotten a discount on your furniture.

I've gone to a store where someone was being rude to the employees. When I walked in with my flat tire the employee said: Do you have our extended warranty? I said no. He said: You'd have bought it if it was offered to you wouldn't you?

He sold me an extended warranty for 10 dollars, and then gave me a brand new tire.

There is plans in the 1950 Amateurs Radio Handbook on how to build 40' supports out of nothing but two by two's or two by fours that supports a 16' - two by two that tilts upward and locks into the assembly. Using 3 boards as a base, you can get your wire antenna 40' off the ground.

The topics covered in the Handbook still applies today with the exception of home brew radios and amplifiers and transmitters and tubes.

Excellent POINT on how a good sales person thinks! THAT person will either own THAT shop one day...or has started his own. I grew up in retail sales. (My parent's owned a IGA supermarket.) My Dad always taught his employee's to "make the customer happy." He said a happy customer is worth gold in FREE good publicity. One unhappy customer can do more damage than you can afford to pay for. Sadly ALL business in the USA today really doesn't care about customer service OR how the customer's feel about THEM.
I enjoyed your comment's.

I see this a great solution. Occasionally, power companies cut down old poles and that could be a source for the two parts you talk about!

John,

I have seen and used a small diameter telephone 30-40 foot pole mounted on the side of a 10 foot one. The 10 foot one was planted firmly in the ground and the top of the 10 foot had a pulley to the to the taller one. The taller one had it's base bolted to a base pivot point of the 10 foot. Easy to tilt up and lower with care. With the treated poles, life is >20 years. The taller one sometimes had the foot pegs.

To follow up on Bills, N7MOG statement, the power company around here do not cut down poles when they are bad they pull them up and replace them. They check the poles with a hammer , a good pole has a certain ring, if bad, they put a yellow ribbon around it and a few days later a crew will come out to replace it. I try to beat them and staple a note on the pole with my name, address and phone number to leave it on the ground. I will come and get it. They had a pole getting too close to a creek washing away one time and installed a new pole, they not only left the old one lay but has a extra old one on their trailer and dropped it on the ground so for two different pole changes I got three poles total. I cut one in two and made a bridge over my ponds overflow but still have 2 poles to use. Now all I need is help to install them, my best radio buddies are all about in their 70's, not too good for setting poles.

Just for your notes ... tilting does work better with a gin pole!!

Dg9bfc

Sigi

As normal, Sigi is right, it is easy to tilt with a gin pole and a little come-a-long. Here is a sketch of one I made 30 years ago with a built in gin pole, This is still in use today as a quick change system when I am building and testing a antenna. It is easy to unbolt and take with you when you move. My large tilt system is direct into concrete but I intend to die here so it is someone else's problem. The next picture in the album is a shot of the base and with double nuts above and below the plate the mast can be set perfectly vertical so it is pleasing to the XYL.

I have a similar story. While I was assembling my QTH in Morgan Hill CA. I needed a pole/tower, etc for my log periodic antenna. Being a old PT&T phone guy, I asked around and the local guy suggested I contact the PG&E foreman. Now the road from San Jose to Morgan Hill was called, "Blood Alley", as it was one of the last of the three lane passing highways. So I asked the PG&E foreman if he might have a solution. His comment was that when they get a vehicle damaged power pole and have to replace it, Well ....so where do you live, after exchanging info I went home. About two weeks later, about noon, I got a call from him and he asked if I still needed one, Yes I said.

OK, he said, "Off line, OK", yes, put a case of Coor's where you what the pole. I took off that afternoon and diligently placed the case where instructed.

YES, and just like Jack and the bean story, that night I came home and found a shortened but beautiful pole in my back yard. Wonders never cease.

This way he didn't have to cut it up for recycling and it didn't go to some unauthorized, use like a fireplace.

Funny how that works out.

Look at the ARRL Antenna Book.

There is probably some articles in the Radio Amateur's Handbook - if you can find one old enough.

You can also research old periodicals such as S-3 Magazine and CQ.

In the 1960's and 70's - there was probably more research done on 11 meter antenna's and antenna designs then any other time in the history of radio.

G5RV - sounds like you don't know anything about antenna's!

A 3 Element Beam antenna, about 300' off the ground would be a good performance antenna on 160 meters!

LOL

[quote] Cheap, but effective and easy to install and
maintain - that shouldn't be too much to ask for...

You are asking a lot from a piece of wire that will probably only be a couple of feet off the ground.

How about a radio tower sitting on a glass ball, shunt fed, it might only need to be about 280' tall?

If you want to talk and be able to hear others on 160 meters, you need to have a lot of copper up in the air as high as possible.

About the only compromise antenna I can think of would be the BaRker and Williamson BWD 90 Folded Dipole antenna. Even with that, you would need some poles 60' tall and a good amplifier and an antenna tuner.

Rich: I am on my 4th IC-735 in my 36+ years as a ham. FINE rig...for it's age and technology. I will assume you know about the VCO plastic trimmer problem that the 735 is "famous" for. (If not, E-mail me and I will fill you in.)

This list's the 735 Antenna Jack Problem.

http://www.dublerfamily.com/Regina_oceani/Manuals/Electronics/Ham%20Radios/ICOM%20IC-M735/IC-735%20most%20common%20service%20questions.pdf

Here is the 735 Service Manual.. It will take 3 to 5 minutes to download-it's a big file so be patient. (It'a 149 pages!)

http://www.fujiyachts.net/manuals/Icom%20IC-735%20Service%20Manual.pdf

(Pictorial on page 7-6 (Actual page 56), shows the connection in upper left.)

FYI-IF the link's don't automatically load when you "click" on them...cut and paste them to your browser. I had had an issue with some people I send stuff to. (But ONLY if they are using Internet Explorer as their browser.) Haven't been able to work that "bug" out-yet!

Hope this helps. Good Luck!

73,

Dave-KJ4PF

Hi Dean, Yes you can "JUST" get a 40 meter delta on the 45 foot mast. Each side would be about 47 feet long and you need 41 foot top of apex to the middle of the bottom. Actually this is a bit too low for the bottom.
I would suggest making each sloping side about 40 feet long and the bottom 60 foot . This will be more a right angle delta. You can feed it at the apex or middle bottom with good results for horizontal. Feed it 1/4 wave down from the apex on one side or at a lower corner for more vertical polarity.
If you space the apex away from the mast 2 to 3 feet and the bottom away also it should work well with less coupling to the mast. Several articles of slightly sloping vertical deltas have been in the ham mags with good results.
It will probably have a feed impedance of 90 to 130 ohms, lots of placement variables, so a 1/4 wave of 75 ohm then 50 ohm to the transmatch will work. Or balanced feed line to the transmatch.

Let us know how it works.

Going to feed it at one side of the corners for low angle take off. I’m putting a 4:1 current balun on it and the feedline will be LMR 400 as that is what I have. To space it a foot or so away from the tower I will have to lower the tower. Not sure what I’m going to space it with. I want to make the bottom of the loop at least 7 feet off the ground for good antenna safety.

Can I feed it with ladder line instead of coax and put the ladder line into the 4:1 current balun close to the house.

Yes you can use ladder line and the balun close to the house. Spacing at top can be with a piece of 2 X 4 lumber secured to the tower and a pully at the end away from the tower. Or if you have a pully and rope now just don't pull the apex all the way up and pull the apex out by pulling the bottom out.
If you have a band that is hard to get tuned, then add 1/8 wave more ladder line at that band and try it. Usually the match box will tune except at very low or very high loads. So adding a little line changes the impedance at the matchbox just enough to get a match. Anything SWR under 2.5 to 1 will usually be enough unless you have a really cranky transmitter.Some just don't like 2 :1 or more.

From: Richard Schmuke
Topic: 33369 Message: 33373

You have different options with a delta loop. It is a 100 ohm antenna and needs a 2:1 balun or a 75ohm matching section. Another way to use coax is to make it 80M in size and it is a 200ohm antenna at 40 thru 6 then use the 4:1 current balun at the feed point and it will be a multiband antenna and do 40 thru 6 with low SWR and 80M at 2:1 swr. If you use ladder line you can have the balun at the tuner with a short section coax. I had a 4:1 x 1:1 switchable balun because different balun were better on different bands with ladder line.

4 to 1 balun will make the impedance awful low. 20 to 30 ohms only. All my delta loops I fed with the 1/4 wave of 75 ohm line, then any length of 50 to rig SWR was dead flat and decent at the band edges.

One of our local hams asked a question on the repeater a couple of days ago.. what sort of antenna will work in his attic? Well, I suggested a delta or "square" loop painted to match his house on the exterior wall. It would be almost invisible unless you walked right up to it and touched it.. and even then may be invisible. His townhouse is an end unit on his strip of townhomes... so that means he could (in theory) put up a whole 80 meter loop running it down the edge of the front... go around the corner and so on.. That should cover 80-40 etc.. rather nicely with a good tuner. Throw in a 2:1 or 4:1 balun, and you are home free... will work better on some bands than others.... and probably would need to be put up at night, fed with latex covered feedline (to match the house again) - fed from one of the top corners...

KK4QDZ - Now with Extra Class Priv's, and a tiny KX3 to enjoy them!

Thank you for all your help I found two bad soldier joints at the antenna jack.

One was on the back side of the board.

I happy now

Richard

Rich: I am on my 4th IC-735 in my 36+ years as a ham. FINE rig...for it's age and technology. I will assume you know about the VCO plastic trimmer problem that the 735 is "famous" for. (If not, E-mail me and I will fill you in.)

This list's the 735 Antenna Jack Problem.

http://www.dublerfamily.com/Regina_oceani/Manuals/Electronics/Ham%20Radios/ICOM%20IC-M735/IC-735%20most%20common%20service%20questions.pdf

Here is the 735 Service Manual.. It will take 3 to 5 minutes to download-it's a big file so be patient. (It'a 149 pages!)

http://www.fujiyachts.net/manuals/Icom%20IC-735%20Service%20Manual.pdf

(Pictorial on page 7-6 (Actual page 56), shows the connection in upper left.)

FYI-IF the link's don't automatically load when you "click" on them...cut and paste them to your browser. I had had an issue with some people I send stuff to. (But ONLY if they are using Internet Explorer as their browser.) Haven't been able to work that "bug" out-yet!

Hope this helps. Good Luck!

73,

Dave-KJ4PF

What does it say about your business when you allow foul-mouthed customers to ruin everyone's shopping experience?

Your dad is right if foul-mouthed people are a leader and everyone will follow them to Kroger.

That doesn't match my life experience.

If you're right we'll see a news article someday that Kroger went out of business. They let all the obscene customers migrate to IGA.

On Wednesday, July 23, 2014 7:20 PM, "David V Colton DVC3565@aol.com [ham-antennas]" <ham-antennas@yahoogroups.com> wrote:

Excellent POINT on how a good sales person thinks! THAT person will either own THAT shop one day...or has started his own. I grew up in retail sales. (My parent's owned a IGA supermarket.) My Dad always taught his employee's to "make the customer happy." He said a happy customer is worth gold in FREE good publicity. One unhappy customer can do more damage than you can afford to pay for. Sadly ALL business in the USA today really doesn't care about customer service OR how the customer's feel about THEM.
I enjoyed your comment's.

The people in a small business are like a family to each other. They're all going to stick up for each other. Joe, let's say I want to use foul language to your family, how much do you generally charge for that right?

The best thing for the morale of a business is to fire the disgruntled and rude customers. There's 15,600 google links for "fire customers"; it's very well-known.

Turn your argument 100%. If you were nice to people you could have probably gotten a discount on your furniture.

I've gone to a store where someone was being rude to the employees. When I walked in with my flat tire the employee said: Do you have our extended warranty? I said no. He said: You'd have bought it if it was offered to you wouldn't you?

He sold me an extended warranty for 10 dollars, and then gave me a brand new tire.

We are talking about a rest home operator or a group of investors that owns this rest home that has said that they do not permit any antenna's on their premises. No where in the constitution of the United States does it say that if you get sick or if you get old and you have to move to a rest home that the rest home operator has to do anything to accommodate you or your former hobbies.
Amateur Radio for most people is nothing but a hobby.
For 80% of the operators, they never did anything their entire amateur radio career except use it like a telephone to check into nets and talk like they were on a telephone.
Had this person been an active ham and belonged to a club that had a working amateur radio station, this subject would be moot.
Even the ARRL admits that out of 700,000 licenses that there is less then 5,000 ARRL clubs and only about 26,000 ARRL members in those clubs.
That is less than 10 members per a club...
I read somewhere that the ARRL only has about 150,000 members, that is less then one in 4 amateurs licensed today in the USA, and since the ARRL has members all over the world, I would say it is probably less then one in six.
Buy the guy a handheld radio and give the guy a roll up J Pole antenna and call this topic closed already!

I had a 735 up until two years ago.

Only problem I had with the antenna connector to from the rear connector to the main board. I all of a sudden lost all receive and transmit capability.

You can check to see if the connection to the SO-239 is the culprit by seeing if you connect an antenna (or just a piece of wire) to the rear panel receive jack. If you hear static or signals you know the connection to the SO-239 is bad.

You may be able to fix it without taking it all apart by bridging the broken connection with wire and solder. That is what I did. It lasted another 29 years.

I once made a small 1watt transmitter and used a 100 watt light bulb for a dummy load to test it. Tuned my shortwave receiver to the signal, and was surprised to make a contact! I told another ham about it, and he tried it, and it worked for him too.

Mel,

Take a look at my QRZ page (KK4GGL). The wire could just run along the top of the fence as opposed to under the porch roof.

If the fence is long enough, you could just put up a dipole, with the wire attached to the top of the fence. You might have to use an automatic or manual tuner at the shack, and 1:1 balun along the way to get rid of the common mode.

You might be able to run a wire up one of the trees, especially if you can put some radials under the grass.

Well....maybe not.

> Not to mention It needs to be inexpensive and very stealthy.

Make it out of #36 black enameled wire and no one will see it from 5 feet
away, even when they know it is there.

> Definitely seeking advice on whether this antenna is a good choice for MARS or a
> bad choice for MARS.
>
> Right now I need to know it is a GO or NO-GO and why.

Bad choice: no-go.

End fed wires "work", yes, but usually on only one frequency or a very
narrow slice of frequencies, depending on their length.

Furthermore, since you must bring an "active' end of the antenna into the
shack, there is almost always lots of RF floating around in the shack and
other places in the home where you would least want to see it.

Impedances vary from very high to very low, again depending on the
frequency and the length of the wire. Like from 2 ohms to 10K ohms.

They are strictly an emergency antenna, to be used when absolutely nothing
else can be used. And then you have to "mess with them" to get them to
work even reasonably well.

IMHO, they aren't worth the effort for what you want to try to do.

Too vague a problem statement, Too many unstated variables

Installation specifics? (Height . configuration(level, slopping, bent).
terrain)

Operating Specifics: Power? Just a participant on a MARS net where folks
will dig you out of the mud or net control where EVERYONE needs to hear you

In general this is a compromise antenna (as are most any "all band"
antenna). Running 100W and this antenna (or most any antenna) you will
not be the loudest station on the band on 160M or 80M and you will do OK
on 17 and 20 if your patient when it comes to working DX. Without good
RF ground (not AC ground there is a big difference) RF in the shack
may(or may not) be a problem. . The ability of the tuner to tune the
thing will be a function of the installation (impossible to predict).
If you find it wont tune on a certain band the addition of 10' to 30' of
feed line will likely solve the problem.

OK I give up

In general this antenna will not work (make you heard) any better or any worse than any other 98' piece of wire strung at the same height fed with ladder line and a tuner. . Despite all the hype antennas unlike radios don't play the same from one installation to another installation specifics, the laws of physics and Maxwell's equations win in the end.

The ability of your antenna tuner to match to it will be a function of the coax length and will vary by height of installation and ground conductivity and is generally impossible to predict although a good modeling program might give you insight. At an installation height of 20' you might get a good match and at 50ft it wont tune on a certain band or vice versa.

Don,t be fooled by fancy names or model numbers. for simple manufactured wire antennas. Keep your money in your pocket, and build your own. There is no such thing as a "Magic" antenna. Many manufacturers would like you to believe that their antenna is the answer to your prayers, but the only thing you will get is a lighter pocket!

Here,s a good place to start from the ARRL. There are many other websites out there with lots of information about end fed, random wires etc.

https://www.arrl.org/files/file/Technology/tis/info/pdf/0683033.pdf

Definitely agree. Homebrewing most wire antennas is pretty easy and generally not too time consuming The ARRL antenna manual has many designs you can try. I have homebrewed many different types from slopers for low bands, resonant dipoles, inverted Ls with homemade coax traps for low bands, K9ay receiving loops, even v beams. Each worked to the degree that design physics, obstructions, space, and terrain, location, and height allowed. I see one of the only reasons to buy commercial antennas wire or any other type of antenna is that you don't have the time to build them, career, family, business obligations, etc.

Good luck!

33412. RE: [ham-antennas] End Fed Long wire Antennas

Yahoo group: ham-antennas (2014)
Date: 2014-07-31 16:12:23 UTC
From: John Murphy
Topic: 33409 Message: 33412

Keith,

I agree. When I lived in another QTH (North Dakota, and a town that was only about 2000, so no Home Depot, no Lowes, nor any other so called ‘Big Box’ store), and the closest Wallyworld was 80-150 miles away, and buying most often was NOT an option.

The closest ‘candy store’ was either in Minnesota or Colorado, and sometimes shipping would equal the purchase price of whatever I had ordered. I did some shopping on line for stuff I could not build like radios, scanners etc, and via phone calls, but when it came to antennas, I usually built my own. I had a 80 meter dipole that I had at about 30-40 ft., and a 20 meter dipole that I had a about 20-25 ft. Both were made out of scrap wire that I found at thrift stores. I also had a homebrew ground mounted vertical that I had seen someone somewhere wrote up in an article.

When it came to connectors I simply went to the local hardware store and started browsing and looked at everything with a different eye (could this be used for that, or could that be used for something else), that sort of thing.

Antennas are so dependent on the installation location that many times when I see questions such as this one posed by <mailto:emrops@...> emrops@... (sorry haven’t seen a name yet or call yet), I get frustrated because he (or she) has not told us the installation method, like from the house to a nearest tree, in a V configuration, on sloping ground, etc. All that matters when you place an antenna.

To emrops@..., I too am in MARS, and now live in a restricted community, but by using my attachment to MARS, and the fact that ham radio is used by DHS, FEMA, as well as local and state agencies, I did get permission to put up a ground mounted vertical (yes the same one I mentioned above). While the same antenna, it does not function the same as it did up in ND, because of the different soil conditions, where it was mounted then vs now, etc. Location and installation does make a difference, I am living proof of that.

I now participate in my MARS activities as I can, when the propagation is right, and so forth. I do digital as well as voice. So the old adage of do what you can, with what you have still is as applicable today as it was when ham radio was young. Better to build it rather buy it…so much cheaper and you get a feeling of well done when you build and it works.

Just my 0.02 in this discussion.

Yes the prices people ask for dipoles and end fed antennas can be pretty high.

There isn't much that can go wrong with a wire antenna as long as you can handle a tape measure, know the length equation that was uses in your license test and can solder.

The basics of any wire antenna is get it as high as possible. For a wire vertical use as many radials as possible even if they are not straight or a 1/4 wavelength.

A reasonably resonant dipole wire antenna can almost always be tuned with the tuner that comes with most transceivers these days. A simple MFJ or LDG tuner is a good option too.

The same goes for EFHW antennas where a balun will probably be needed. For 100 watts and below they can be made cheaply.

From: Richard Schmuke
Topic: 33415 Message: 33415

Mr Murphy has struck . Working on a 30M vertical. Coax has just been checked with a Tektronix 50ohm termination and checks OK.

Antenna has a 8ft raised feed point so only 3 to 4 above ground, sloping radials are needed. I have 8 , four 12ga copper and four 18ga silver. The radials are cut to 23ft 1 inch and aluminum tube vertical element is also set at 23ft. The system checks at 1.5:1 swr at 8.8 MHz with a MFJ-259B. 23ft and 8.8 Mhz?

Any ideas ???

Rich , Kd0zz

Looking at charts too long and you will get analysis paralysis

33416. Re: [ham-antennas] Problem

From: Mel Farrer
Topic: 33415 Message: 33416

HI Rich,

Not sure why you are seeing 8.8 unless the length of coax is doing something funny. I would check the antenna at the feedpoint. I modeled it with your dimensions and came up with a little over 10.25 MHz 37ohms j0. When you drop the ends of the radials closer to ground the impedance does go up from 37 ohms with them level. But not much I got 1.2:1 at 10.125 with 23.6 ft radials ends at 2 ft. and 24.25 feet for the vertical element. Ground and surrounding junk has an effect also. Some thoughts.

Mel, K6KBE

From: soona4sail@...
Topic: 33409 Message: 33418

After my original post, about building your own end fed or wire antenna, I came across another interesting site, about building your own simple long wire antenna.

It,s a good read, and has simple plain instructions on getting you up and running. I,ve been doing radio for 40 years, and I think I will give it a try myself. Looks like fun, and should be no more than a two brewsky job, and change out of a $20 bill.

At the very least, it would be a great field day antenna, and I,m sure you could add extra feet of wire as space allows.

Most important part will be the little balun. Take your time, and follow the directions

My only bad experience was in GA, and the only wire available on my budget was aluminum. WELL, during a really bad winter icy storm in the morning, the signals were really poor. I could not load the transmitter so went out to look at the antenna, what antenna??? From the roof insulator the wire went straight down to the ground and stayed there all the way to the end at the tree. 1 inch or more of radial ice. Never make a antenna out of soft aluminum wire. Lesson learned.

I have quietly followed this thread with some surprise. I have an offset fed Dipole, for 10-80 meters, an end fed Dipole 6-80 meters, and am working on a 43 foot vertical (diploe inside fiberglass pole). So far I have not seen a great deal of difference between the offset Center fed and the end fed dipoles. Most of you have more time and experience in amateur radio than I have, only having been licensed for 3 years now. But with my General class priviledges I have worked my share of long distance stations on both types of antennas and my ICOM 746 PRO.Your comments are a surprise to me with the results I have had here in North Carolina. I guess I will continue to defy physics and enjoy my end fed dipole and not worry about why

Planning to put up a Vertical for 40m and 10m , or try to load one 40-10, yes would like to run it on all HF bands, have Trees to shoot up a wire or will put up either Telco or Conduit /EMT poles for a mast , how high not sure yet, no restrictions except budget and not too ugly for XYL, ,
What do you guys use ,like ,recomend , I do not want to put up a full metal tower , want to go as low profile as possible ,just a personal preference and not to draw attention .
At this time i use a Off Center Fed running East /West, for 80-10, only run 5 watts, but will have an amp built by this winter . This Vertical is for Checking into Nets and DX for fun, not a serious contester , i am done with all Rat Race stuff , Ham Radio for me is just Fun . Will consider a portable vertical as well, but do not know if practical . Thanks, AJ W5heh

My only antenna is a 55 foot tall vertical with 4 radial/ground wires, each 66 feet long. It is made of nested aluminum tubing, and an aluminum rod at the top, and has been held up with cotton clothes-line rope for at least 15 years. I mount it on an insulator made out of bits of PVC plumbing pipe.

The antenna has a combination trap/loading coil at the 33 foot level. It was orginally designed to be an 80/40 meter antenna which would also work on 15 and 20.

It is fed at the bottom with a section of buried RG-8.

Using a home-brew antenna coupler, I use it on all bands, including the WARC bands. It tunes to 1:1 SWR.

To use it on 160 meters, I have to add a small coil, made of #12 wire on a 4" diameter ceramic form, as a bottom-loading-coil. I have to switch it in for 160, and out for all other bands.

On 160, I have worked Europe from North Idaho with 100 watts.

I have also made DXCC (still waiting for the certificate), mostly on 20, but also some on every other band.

I use it every day for my NTS duties, and feed it with 600 watts. I don't have an amp for 160.

I have also used it successfully with an SMK-1, 350 mW output, on 40 meters and have worked all up and down the west coast with that and into Texas.

I would seriously consider the 43' wire (otherwise supported
vertically) and a very good tuner. (possibly in a telescoping fiber
glass tube set {~40 feet})
(the tube set are not too bad if bought properly)

Hihi , misspelled Vertical ! Thank you Ken, Ron, Mike, and the details ,links ,pics, will be of help. Got questions for Ken, first- you mentioned - bits of pvc for mounting driven element or at ground level ? any pics you have would help a lot, do you use a tuner ? the 160 meter switched coil, where is that mounted inside your nice looking shack or ? (switch is what type ?), you have cool looking Heath kit Equipt. !! . Tnx for much detail you gave me .
Ron, on 43 wire, with radials and how long and number of them? any articles you recommend ? How Far or mounting method could i use with my Tall Trees ? Will consider Fiber mast you mentioned ,just concerned about 50 Mph winds we get infrequently . Would not that mast to fall on our Family Milk Cows ,hihi. Tnx Ron.

Mike, Helical Mag-Loop, how high up is appropriate ? I did buy some old air Variable Caps. to build one this winter for fun to see if i can use it during our lightening Storms here in the Ozarks . Mike Tnx.

Any others please chime in , appreciate this Group, Antennas are a major part of my Transmission , Thanks & 73s, AJ W5Heh

My MFJ (which is not what I would consider really well made) --- First overseas contact was at 5' elevation in the back yard at 5-8 watts on a KX3 to northern Italy on 15 meters....SSB no less.

Does that count?

KK4QDZ - Now with Extra Class Priv's, and a tiny KX3 to enjoy them!

Well, this morning i pulled the trigger on the LDG 31' portable Vertical, is on sale at Cheapham for 75.oo, the 43 footer is 125. , but to heavy for portable, so i will run a Vertical wire up in one of our Trees, will utilize either a Petoway Coil or Radials or both if needed for both . Looking forward to setting it up and experimenting with the Shack Wire ,will find the Tallest Tree , hoping at least 40ft. Any suggestions /advice will be appreciated . 73s, AJ W5heh

ps yes will update how it goes !

I have only read favorable reports from others here and I put one up
fed with a Yaesu FC-40 + FT-857D and it worked good on 6 and 10 meters,
a steel fireplace was the counterpoise, (then I went on vacation) you
should use 120 radials 1/4 wl on the lowest frequency you wish to use.
(or the frame of a car or pickup truck)
The fiberglass extendable pole can be unextended as desired at any time,
but generally they are quite rugged and flexible.

Yes. When I first installed this vertical, I used an empty wine bottle as the base insulator. A couple of years ago, I went out back to look the vertical over a bit more closely, once the snow was gone, to see why the "guy wires" were a bit slack.

I found the wine bottle shattered and the bottom end of the vertical, with the coax connection to it, buried at least 6 inches into the dirt.

What amazed me was that there was no difference in how it loaded nor its operation. The only conclusion I could come to was that the ground there was a pretty good insulator. (!)

So I made a better, more robust, insulator out of pieces of PVC pipe.

> any pics you have would
> help a lot,

OK. I'll take some...

> do you use a tuner ?

Yes. A home-brew tuner which I have had for years. I built it many years ago. It has a rotary inductor, two large capacitors, and many fixed capacitors. It has an SWR bridge built into it, and switching for three antennas.

> the 160 meter switched coil, where is that
> mounted inside your nice looking shack or ?

No. It is out at the base of the antenna and is remotely switched from the shack.

> (switch is what type ?),

It is a large relay.

> you have
> cool looking Heath kit Equipt. !! .

Well, I have retired the SB-102 until such time as I can completely rebuild it since that photo was taken. I have several other rigs I can use now.

> Tnx for much detail you gave me .

Sure. Glad to help.

OK FOLKS:

Here are the rules of the reflector : HAM-ANTENNAS
This file will be sent once a month automatically to remind all users.

1. Name calling (race, religion, politics, gender, etc.), is prohibited.
2. Telling someone they are ignorant (in any way, shape, or form), is prohibited.
3. Denigrating other races or minorities, or expressing POLITICAL VIEWS will earn you moderation or banning.
4. If you do it privately it is a private dispute. When/if it spills over onto the reflector, you will be moderated or banned.
5. Even coming close to these boundaries is to be avoided.
6. Banning/moderation will be used, with NO notification to the transgressor.
7. Civil chatter and Civil wordage is THE rule.
8. IF the Moderators are offended, then penalties will be applied.
9. There are two Moderators, EITHER can ban/moderate you.
10. Moderators ARE the final arbitrator of disputes, we hate bickering!
11. USE Private or Direct Emails to address your concerns to the Moderators, because public postings may likely result in penalties as above. !!!!
12. Use common sense. If you would be hurt or upset if you received what you are about to send, and you are intentionally meaning to do that, DON'T DO IT!

13. We ALL would like to enjoy discussion about HAM-ANTENNAS, nothing more.

Don't you just love it when a no code Technician comes along and starts using CW terms to make it sound like he is a class A Operator.

The HIHI stuff should be left at the front door when you talk two meters FM or on an internet forum.

The only Verticals I use are for 10 meters and FM.
I have a Hustler 5 BVT, but it's performance is lackluster at best!

Unless you had a 300' tower, there is no way I would recommend anyone trying to work 160 meters with a vertical.

Was it a champagne bottle? They're usually stronger.

I wonder if filling the bottle with some sort of polymer, say a quart of fiberglass resin would have helped or hindered? One would want a polymer that neither expanded nor contracted on curing. Such a polymer may not exist. (I know of metal alloys with this property, but we want a dielectric here.)

Anyone have any experience making their own ceramic insulators?

First, find someone with a pottery hobby. (Much like the recipe for rabbit stew.)

> What amazed me was that there was no difference in how it loaded nor its
> operation. The only conclusion I could come to was that the ground there
> was a pretty good insulator. (!)

I agree. Maybe it was sitting on a pile of glass shards, too.

> So I made a better, more robust, insulator out of pieces of PVC pipe.

Probably a better scheme, but you wouldn't get to guzzle the champagne! (Champagne, buckwheat crepes [bliny] with sour cream and cherries -- breakfast of champions!)

Hmmm, take wine bottle, coat inside with mold release, fill with polyester resin + lots of fibers + catalyst, let cure, break off bottle. A quart of resin (more than enough) is about $15 at amazon. Or use 1L plastic coke bottle. Hmmmm. Cut the bottom off, fill it from the big end.

Another free idea from the fertile compost heap of my mind: bowling balls. See this page: https://www.sff.net/people/j.oltion/trackball.htm Imagine a bowling ball, with a socket drilled out to accept the bottom of a vertical. For permanent installation, make some sort of ring for it to rest in. For field use, just set it in a depression in the ground. Use guys. Get clever: put a little bullseye level in the ball. Drilling out the socket is /not that hard to do/ although I have never tried. BTW, telescope hobbyists have all kinds of swell ideas for mounting things. A bowling ball weighs around 15 lbs, diameter ~8.5 in. See https://en.wikipedia.org/wiki/Bowling_ball for the inside story.

33437. Problem Solved

Yahoo group: ham-antennas (2014)
Date: 2014-08-02 01:11:12 UTC
From: Richard Schmuke
Topic: 33437 Message: 33437

After beating my head on a rock for a few days and trying to get my MFJ-259B to give me good readings on my 30M vertical, I rechecked it to a known good 50ohm calibration load, OK thru the whole range, checked out my 160M loop on all bands , checked out my NA4RR hex beam on its bands. No problem, all good with the MFJ-259B. Went back to my vertical, and who can't build a mono-band vertical? I have made several, all different bands. The 30M vert is bad. I then took the advice of those wiser than me and got out my 35 year old Swan SWR meter. Gee the Swan likes the antenna as does my radio. MFJ-259B does not like to operate on 10 Mhz in the middle of Missouri, must be a defect in the grey matter. That is the grey matter caused at the solder joints for not using lead any more, no personal defective grey matter that I can remember.

The above post can be fictional, hypothetical, or downright nonsensical.

I have a 43' vertical on the roof. It is fiberglass and the 12g wire up the middle is solid. Stranded should not be used for transmitting. If you elevate the feed point and radials you can eliminate 75% of them. MFJ-928 auto tuner at the feed point. See my QRZ. 73 de dave/kd6il

Dave , you are Funny! and gave some usable tips ,details that i will have to investigate , Thanks, 73s, AJ

ps seems like some do not motivate well like you , they ASSume your an inexperienced newbee, HIHi , (let's see now i belong to at least 4 QRP CW type groups, yes ,my CW is rusty, but improving every day !), will not help Grow the Hobby that some give negative feedback , why do they bother ? , glad i have thick skin, and will GrandFather my CW General,from my teen years in 11days, at next club meet.

Closest cell tower is 3.5 miles and AM broadcast is about 12 miles. Closest neighbor is half mile so I am lost except MFJ does not like 10Mhz.

How close is your nearest Broadcast Band Transmitter ?? They can do a number on the MFJ

Analyzer.

Subject: [ham-antennas] Problem Solved

After beating my head on a rock for a few days and trying to get my MFJ-259B to give me good readings on my 30M vertical, I rechecked it to a known good 50ohm calibration load, OK thru the whole range, checked out my 160M loop on all bands , checked out my NA4RR hex beam on its bands. No problem, all good with the MFJ-259B. Went back to my vertical, and who can't build a mono-band

vertical? I have made several, all different bands. The 30M vert is bad. I then took the advice of those wiser than me and got out my 35 year old Swan SWR meter. Gee the Swan likes the antenna as does my radio. MFJ-259B does not like to operate on 10 Mhz in the middle of Missouri, must be a defect in the grey matter. That is the grey matter caused at the solder joints for not using lead any more, no personal defective grey matter that I can remember.

The above post can be fictional, hypothetical, or downright nonsensical.

Rich, Kd0zz

33447. MFJ Analizer

Yahoo group: ham-antennas (2014)
Date: 2014-08-02 13:58:07 UTC
From: Art Nienhouse
Topic: 33447 Message: 33447

Hi Richard
Years ago I lived 20 miles from WLS am tower between my house and the TX tower, there were interstate power lines that were between my house and the tx tower I think the distance from the WLS tower was about a mile as was the distance my house was from the power lines to my antenna.
WLS .890am clear channel signal would hitch a ride on the interstate power lines 20 miles from the tower and over powering the car radio when driving under them. When the interstate power line insulators were changed out after so many years of service a lot of QRN was eliminated.

When I tried to use my MFJ analyzer on my 40 /160 & 80 twin element 1/2 sloper it worked ok on all frequency's but 160 meter I would see the meter if attenuated enough bouncing to the broadcast signal peaks, when not attenuated the MFJ meter was just pegged.

The solution was a ICE broad cast band filter (model 402x) 1.8 -30 Mhz (300 w) 50 ohm Non-Polar Non-DC Passive.....Contest guys use this filter it will keep everything out below and above.
MFJ used to sell a coil kit you put on the analyzer I have one somewhere but never used it.

I found the FET that runs the MFJ to be (very sensitive to RF) any RF, if the analyzer was on the table next to the amp it would fry, and it needing a trip to Starkville MS for a $60 repair, this happened twice the first time it was connected to a Alpha Delta coax switch but not switched in line, the second time just sitting near the Command Amp..... not connected via coax at all and not even on..... another $60 dollar trip to Starkville.

This is a very useful tool but has its faults, now I keep it in the closet ten feet away from the station equipment, and many years later its still working just don't let alkaline batteries in it for a long time they will corrode.

Regards
Art

From: Richard Schmuke
Topic: 33447 Message: 33448

Good information Art, I find the MFJ is handy for me and the price was affordable. This experience working with 10Mhz was something new. My analyzer seems to be OK on all the other bands. The closest AM station tower is low power and about 12 miles away.

I find batteries in a large pack from Costco a good value, everything takes AA's.

Rich, Kd0zz

I wondered the same thing Joe, my 160 loop and 6 band hex beam are all stranded.

Rich, Kd0zz

Subject: Re: [ham-antennas] Digest Number 3610

Why would stranded not be used for transmitting?

Hihi , misspelled Vertical ! Thank you Ken, Ron, Mike, and the details ,links ,pics, will be of help. Got questions for Ken, first- you mentioned - bits of pvc for mounting driven element or at ground level ? any pics you have would help a lot, do you use a tuner ? the 160 meter switched coil, where is that mounted inside your nice looking shack or ? (switch is what type ?), you have cool looking Heath kit Equipt. !! . Tnx for much detail you gave me .
Ron, on 43 wire, with radials and how long and number of them? any articles you recommend ? How Far or mounting method could i use with my Tall Trees ? Will consider Fiber mast you mentioned ,just concerned about 50 Mph winds we get infrequently . Would not that mast to fall on our Family Milk Cows ,hihi. Tnx Ron.

Mike, Helical Mag-Loop, how high up is appropriate ? I did buy some old air Variable Caps. to build one this winter for fun to see if i can use it during our lightening Storms here in the Ozarks . Mike Tnx.

Any others please chime in , appreciate this Group, Antennas are a major part of my Transmission , Thanks & 73s, AJ W5Heh

My MFJ (which is not what I would consider really well made) --- First overseas contact was at 5' elevation in the back yard at 5-8 watts on a KX3 to northern Italy on 15 meters....SSB no less.

Does that count?

KK4QDZ - Now with Extra Class Priv's, and a tiny KX3 to enjoy them!

Well, this morning i pulled the trigger on the LDG 31' portable Vertical, is on sale at Cheapham for 75.oo, the 43 footer is 125. , but to heavy for portable, so i will run a Vertical wire up in one of our Trees, will utilize either a Petoway Coil or Radials or both if needed for both . Looking forward to setting it up and experimenting with the Shack Wire ,will find the Tallest Tree , hoping at least 40ft. Any suggestions /advice will be appreciated . 73s, AJ W5heh

ps yes will update how it goes !

I have only read favorable reports from others here and I put one up
fed with a Yaesu FC-40 + FT-857D and it worked good on 6 and 10 meters,
a steel fireplace was the counterpoise, (then I went on vacation) you
should use 120 radials 1/4 wl on the lowest frequency you wish to use.
(or the frame of a car or pickup truck)
The fiberglass extendable pole can be unextended as desired at any time,
but generally they are quite rugged and flexible.

Yes. When I first installed this vertical, I used an empty wine bottle as the base insulator. A couple of years ago, I went out back to look the vertical over a bit more closely, once the snow was gone, to see why the "guy wires" were a bit slack.

I found the wine bottle shattered and the bottom end of the vertical, with the coax connection to it, buried at least 6 inches into the dirt.

What amazed me was that there was no difference in how it loaded nor its operation. The only conclusion I could come to was that the ground there was a pretty good insulator. (!)

So I made a better, more robust, insulator out of pieces of PVC pipe.

> any pics you have would
> help a lot,

OK. I'll take some...

> do you use a tuner ?

Yes. A home-brew tuner which I have had for years. I built it many years ago. It has a rotary inductor, two large capacitors, and many fixed capacitors. It has an SWR bridge built into it, and switching for three antennas.

> the 160 meter switched coil, where is that
> mounted inside your nice looking shack or ?

No. It is out at the base of the antenna and is remotely switched from the shack.

> (switch is what type ?),

It is a large relay.

> you have
> cool looking Heath kit Equipt. !! .

Well, I have retired the SB-102 until such time as I can completely rebuild it since that photo was taken. I have several other rigs I can use now.

> Tnx for much detail you gave me .

Sure. Glad to help.

Ken W7EKB

Don't you just love it when a no code Technician comes along and starts using CW terms to make it sound like he is a class A Operator.

The HIHI stuff should be left at the front door when you talk two meters FM or on an internet forum.

The only Verticals I use are for 10 meters and FM.
I have a Hustler 5 BVT, but it's performance is lackluster at best!

Unless you had a 300' tower, there is no way I would recommend anyone trying to work 160 meters with a vertical.

Was it a champagne bottle? They're usually stronger.

I wonder if filling the bottle with some sort of polymer, say a quart
of fiberglass resin would have helped or hindered? One would want a
polymer that neither expanded nor contracted on curing. Such a polymer
may not exist. (I know of metal alloys with this property, but we want
a dielectric here.)

Anyone have any experience making their own ceramic insulators?

First, find someone with a pottery hobby. (Much like the recipe for
rabbit stew.)

> What amazed me was that there was no difference in how it loaded nor its

> was a pretty good insulator. (!)

I agree. Maybe it was sitting on a pile of glass shards, too.

> So I made a better, more robust, insulator out of pieces of PVC pipe.

Probably a better scheme, but you wouldn't get to guzzle the champagne!
(Champagne, buckwheat crepes [bliny] with sour cream and cherries --
breakfast of champions!)

Hmmm, take wine bottle, coat inside with mold release, fill with polyester
resin + lots of fibers + catalyst, let cure, break off bottle. A quart
of resin (more than enough) is about $15 at amazon. Or use 1L plastic
coke bottle. Hmmmm. Cut the bottom off, fill it from the big end.

Another free idea from the fertile compost heap of my mind: bowling
balls. See this page: https://www.sff.net/people/j.oltion/trackball.htm
Imagine a bowling ball, with a socket drilled out to accept the bottom
of a vertical. For permanent installation, make some sort of ring
for it to rest in. For field use, just set it in a depression in
the ground. Use guys. Get clever: put a little bullseye level in the
ball. Drilling out the socket is /not that hard to do/ although I have
never tried. BTW, telescope hobbyists have all kinds of swell ideas for
mounting things. A bowling ball weighs around 15 lbs, diameter ~8.5 in.
See https://en.wikipedia.org/wiki/Bowling_ball for the inside story.

OK FOLKS:

Here are the rules of the reflector : HAM-ANTENNAS
This file will be sent once a month automatically to remind all users.

1. Name calling (race, religion, politics, gender, etc.), is prohibited.
2. Telling someone they are ignorant (in any way, shape, or form), is prohibited.
3. Denigrating other races or minorities, or expressing POLITICAL VIEWS will earn you moderation or banning.
4. If you do it privately it is a private dispute. When/if it spills over onto the reflector, you will be moderated or banned.
5. Even coming close to these boundaries is to be avoided.
6. Banning/moderation will be used, with NO notification to the transgressor.
7. Civil chatter and Civil wordage is THE rule.
8. IF the Moderators are offended, then penalties will be applied.
9. There are two Moderators, EITHER can ban/moderate you.
10. Moderators ARE the final arbitrator of disputes, we hate bickering!
11. USE Private or Direct Emails to address your concerns to the Moderators, because public postings may likely result in penalties as above. !!!!
12. Use common sense. If you would be hurt or upset if you received what you are about to send, and you are intentionally meaning to do that, DON'T DO IT!

13. We ALL would like to enjoy discussion about HAM-ANTENNAS, nothing more.

When I receive an email from these two groups in .....yahoogroups. com, all that shows in the "from" column is "Name, From" with no ID as to the sender. I can tell where it is coming from as the subject line shows what group it came from. Very annoying. Most other groups show the senders name.
Any ideas?

"Richard Schmuke" richdjschmuke

After beating my head on a rock for a few days and trying to get my MFJ-259B
to give me good readings on my 30M vertical, I rechecked it to a known good
50ohm calibration load, OK thru the whole range, checked out my 160M loop on
all bands , checked out my NA4RR hex beam on its bands. No problem, all good
with the MFJ-259B. Went back to my vertical, and who can't build a mono-band
vertical? I have made several, all different bands. The 30M vert is bad. I
then took the advice of those wiser than me and got out my 35 year old Swan
SWR meter. Gee the Swan likes the antenna as does my radio. MFJ-259B does
not like to operate on 10 Mhz in the middle of Missouri, must be a defect in
the grey matter. That is the grey matter caused at the solder joints for not
using lead any more, no personal defective grey matter that I can remember.

The above post can be fictional, hypothetical, or downright nonsensical.

I do my best for K2HT, got him to use LOtW and computer logging, he likes my MFJ-259B so much he got one. He and I conversed several times the last few days about my antenna problem. He is one of the finest but dont let him know I said that, dont want him to get a big head, hihi. The MFJ-259 has been a great help until this antenna.

33450. Stranded Copper Wire for Transmitting

Yahoo group: ham-antennas (2014)
Date: 2014-08-02 15:32:06 UTC
From: soona4sail@...
Topic: 33450 Message: 33450

I have always used stranded wire for transmitting and receiving, and it has worked very well. I

However, with that said, I always use insulated stranded copper wire, and make sure any exposed copper strands, are is completely weatherproofed, either with shrink tubing, liquid electrical tape or both. The worst enemy of stranded copper wire, is moisture, salty air, and all the other elements of nature. Corrosion will build in very quickly.

On the plus side, stranded copper wire has more surface area, and as electrical currents like to flow on the outside of a conductor, it makes sense that stranded copper wire, may be more efficient than solid...or so my Elmer tells me!!

73 John VE7MTW

33451. Re: [ham-antennas] Problem Solved

Yahoo group: ham-antennas (2014)
Date: 2014-08-02 20:53:53 UTC
From: Bill Blomgren (kk4qdz)
Topic: 33437 Message: 33451

If the AM station is directional (and a huge percentage are) - and if that signal is in your general direction.. even low power stations can put big signals out.

Example: WLCY was at the top of Tampa Bay - 5kw 3 tower directional at night. I had problems with them getting into my recording equipment at the Mahafey Theater in Downtown St Petersburg, at least 18 miles away. Despite good (CORRECT) cabling (pin 1 problem not present) -- and so on, I could hear that station while recording the orchestra unless I was VERY careful with grounds on the equipment I took in there. (I was doing digital recording back in the 80's..)

The problem: that 5kw was "aimed" over the very area I was in. And it was booming in more like a 50kw station. You may still be getting significant energy from the am that is 12 miles away.. and that vertical is the ideal antenna for capturing it.

KK4QDZ - Now with Extra Class Priv's, and a tiny KX3 to enjoy them!

Subject: RE: [ham-antennas] Problem Solved

Closest cell tower is 3.5 miles and AM broadcast is about 12 miles. Closest neighbor is half mile so I am lost except MFJ does not like 10Mhz.

How close is your nearest Broadcast Band Transmitter ?? They can do a number on the MFJ

Analyzer.

To: Richard Schmuke
Subject: [ham-antennas] Problem Solved

After beating my head on a rock for a few days and trying to get my MFJ-259B to give me good readings on my 30M vertical, I rechecked it to a known good 50ohm calibration load, OK thru the whole range, checked out my 160M loop on all bands , checked out my NA4RR hex beam on its bands. No problem, all good with the MFJ-259B. Went back to my vertical, and who can't build a mono-band vertical? I have made several, all different bands. The 30M vert is bad. I then took the advice of those wiser than me and got out my 35 year old Swan SWR meter. Gee the Swan likes the antenna as does my radio. MFJ-259B does not like to operate on 10 Mhz in the middle of Missouri, must be a defect in the grey matter. That is the grey matter caused at the solder joints for not using lead any more, no personal defective grey matter that I can remember.

The above post can be fictional, hypothetical, or downright nonsensical.

Rich, Kd0zz

Kieth, You are correct, If I did not have the obligation mentioned, I'd be spending all of my time building antennas.

If that were the case right now, I'd be spending my time building and no time on the air.

Thanks.

The difference between solid wire and stranded wire efficiency would be almost immeasurable. I only mention it to emphasize the point that most electrical activity happens on the surface of the conductor. Many strands of wire have more surface area than a single solid wire.....and thus may carry more current.

By far the best part of stranded wire, to me, has been its supple nature, and ease to work with. It is simple to handle, easy to rollup (field day ops), and performs well as both a receiving and transmitting antenna.

Back when I had a small antenna farm...My MFJ 259B would not work at all on 160m and I almost took my 1/4 reduced sloper down though both my SPE 1k and K3 had no issues with it. Running K3 EZ program on the 160m antenna showed tuned at bottom of band on 160 at near 1:1 and on MFJ 259B pegged at >25:1. At the time I lived a few miles from Tijuana in Imperial beach area and there are some massive AM broadcast stations just across the border. Glad to know the answer to my issue now. Thanks for this thread and knowledgeable hams on it.

Since they are at least 1/2" in diameter, you could not bend a solid one, and vibration would very soon break them.

I agree, stranded wire is easier to work with for antennas. Beyond that it would have no effect on it's transmitting or receiving capabilities.

I'm amazed at how much we over analyze everything today. When I got into the hobby we found wire and made antennas. Put them up and worked the world. Now we have to worry about all kind of things we never even thought about. We actually made antennas without modeling software or antenna analyzers. And it was before personal computers and Internet forums.

Good comments coming back on stranded wire.

The most important thing you can do for any antenna, especially stranded wire antennas, coax braid etc, is to protect it from the elements, ESPECIALLY water. Worse still, is salty air blowing in from the ocean.

Once water gets into stranded wire, coax braid, aluminum slip joints, the corrosion process begins.Copper greens, aluminum powders.....braid in coax will suck up water like a paper towel.

Bottom line, keep a good supply of shrink tubing (buy it in 4 ft lengths from a good quality auto parts store...much cheaper than those little packets from the box store) . I always have a can of liquid electrical tape on hand as well. Use it liberally. Cheap preventive maintenance.

Electrical tapes are ok, but invariably the water gets under the windings, loosens the glue and the tape comes loose. Not a good plan when its, 50 ft up your tower.

Do whatever you can do, to keep moisture out of your stranded wire (I use insulated wire for my antennas), your pl259 connectors, your coax, your traps, your baluns., your aluminum tubing slip joints....and any other parts of your antenna you can think of.

This all started when someone was giving advice to someone about an antenna, and also mentioned that they should not use stranded wire. And thus the question of why not was asked, but never answered.

Yeah, but it's cheaper than a kidney!

List price of the latest MFJ analyzers are creeping upwards, though.
Well over $300 these days. Amazing.

Frederick,

I agree. In the age before computers and the internet, we just grabbed the edition of the ARRL Handbook or ARRL Antenna Book that was available (yes even if it was 3, 4, 5, or 6 years old) read up on what we wanted to do, and then did it. Want put up a dipole …. well go to the (insert whichever book you had access to here), read about dipoles then put one up. And you are right, we didn't worry about whether we had stranded or solid wire, or whether we had to solder or if we could just wrap 500 pieces of wire end to end, and put it up and tried it. If it didn't work, we took it down and remade it and then tried it again, and repeated until it worked.

While I do understand the need of some of the newer hams to get all the information possible to avoid redoing what is thought about, sometimes the trying it and retrying it and repeating until it works like you want IS the learning process, and when it finally works you are proud because you went through that learning process.

When a friend of mine and I were in high school (1972) and got our first novice licenses, we cobbled together a station out of old TV and radio scraps that the repair shops were throwing away, and we eventually found that we learned much more, by doing and redoing and repeating until something worked.

Sometimes a person can overthink a project and it may be months or years (or never) when it gets done. I like Nike's slogan, "Just do it!". If it is antenna, just put it up and try it. If it works, great, if not then take down and rework it until you get it right.

Just my 0.02 worth.

I agree, stranded wire is easier to work with for antennas. Beyond that it would have no effect on it's transmitting or receiving capabilities.

I'm amazed at how much we over analyze everything today. When I got into the hobby we found wire and made antennas. Put them up and worked the world. Now we have to worry about all kind of things we never even thought about. We actually made antennas without modeling software or antenna analyzers. And it was before personal computers and Internet forums.

This is hardly scientific, but the oldest review I found on eham
came from 2003, and the reviewer said he had had the unit "4-5 years",
so call that 1998, or 16 years minimum. In the world of electronics,
that works out to "since dinosaurs roamed the earth."

That's certainly long enough to have recovered their R&D costs, if that's
what you're driving at.

Maybe they can work out a way to cram a USB port into the case, and put
some useful data on it, and accept some useful commands. (And figure
out a battery door. There's plenty of existing technology they could
research for clues about how to make replaceable batteries replaceable
without tools and a clean room. I have some swell ideas on the subject,
having just glanced at a flashlight.)

Compare that with a professional analyzer from hp agilent etc ... and you know how expensive "an arm and a leg" is ...

You can measure not only antennas (like mfj 259 269) ... but also filters

It is a 2 port analyzer

Graphical display

Can be brought to antenna site (for the bigger professional devices you need a truck hi hi)

It is handy, accurate and for what it can do for you it is very cheap

Remember it has over 100db dynamic range!!! Even up to 3 gig!!!

Nwa3 goes up to 1.3 gig but dynamic goes down above 500 megs

And you need a pc with the nwa3!!

So ... for me it was a good buy from china :-)

As an example ... I have some uhf cavity filters (6 cavities in both ways so there are 12 cavities to tune)

With that analyzer it was very easy .... and I could get about 100-120 db damping of the unwanted signal ... with only 2 db inline loss

Without the big dynamic range of the kc901h such a thing is difficult to tune (nearly impossible with nwa3!!!)

The issue with single/ solid wire , is that it could have a tendency to work harden and break at the bends and solder joins
I have used stranded wire on all but 1 antenna , my wire comes from old extension leads , I have never had an issue with them or from the single wire(solid wire), so the argument is a little pointless

It kind of depends on how high the RF current density the antenna has. A short loaded vertical will need to have greater conductance whereas a halfwave dipole doesn't care too much about diameter or stranding. Heck I even ran the small gauge electric fence wire on my coax fed 80m dipole for years as a Novice, worked all the bands with 100-Watts. (Didn't know what mismatch loss was or how it gobbled up my power radiated).

So if we were to look at skin depth for a given frequency and set our depth of RF current density to say 5-skin depths, one could use 27 gauge at 3.5 MHz in copper for a half wave dipole. 5 skin depths at 3.5MHz is 6.88 mils (13.76 mils diameter=27 gauge), 5 skin depths at 7 MHz is 4.87 mils (9.74 mils diameter=30 gauge). I use #26 stranded wire for all of my field ops because it is lightweight and easily spools onto most anything and usually only get down to 40m.

Since Rac = Rdc at approximately 3-skin depths, the dominating resistive component is the DC resistance of the wire. Upon entering these gauges into EZNEC and push the analysis button on many dipole antennas I've modeled, once you get to 26 gauge wire for 80m and above, the gain difference that I can see is factions of a dB. I mean I put in #6 and #26 and see at most 0.7 dB for a dipole. The height above ground, ground conductivity, element orientation play a bigger role in overall gain than the wire size.

Another great resource is N7LF. He published a good read called "Conductors for HF Antennas".

Bottom Line: The amount of current density is the key to realizing if you need bigger wire or not. The shorter the antenna, the higher the current density.

33475. Coax vs RFI ?

Yahoo group: ham-antennas (2014)
Date: 2014-08-04 02:34:23 UTC
From: p_chap@...
Topic: 33475 Message: 33475

Where I live RFI should not be part of the equation, but it is S9 plus 10 on the fourty meter antenna. Today I have been unplugging all suspects from the dozen plus UPS units in the house and unplugging them as well.

One of the sources moved out of the neighborhood, a plasma TV with a modulating machine gun. I think the other one might be me for a couple of reasons. The problem is mainly 40 meters on a dipole. The coax for that antenna lays on the roof, only 5-8 feet from the main wiring bundle going to the two 200 amp breaker panels. The antenna with center insulator and balun is clear of the roof at least 15 ft or so. The 20 meter antenna does not lay on the roof, but is in clear space, coax and all.

Whacked my back out of joint and will be a few days before I trust myself on a ladder again so searching for helping thoughts.

Assuming that we are all familiar that an antenna resonant is going to receive better than one that is not, lets go from there. The 20 dipole on 40 is quite a few db down of course, but no machine gun fire in and out. A little bit of the buzz pulsing, but at a S2-S3 level and I can see signals popping easily and good read to S9.

On 40 with the 40 dipole, When the noise is present 75 percent of the time it is a steady dead on s9 plus 10 and everything competes with that. I can switch to the 20 dipole and have clarity for SWL, yet lose them in the rapid fire on the 40 dipole.

Logic tells me to get the coax further away from the wiring bundle going to the panels.....comments???? or other ideas would be welcome.....

The very first thing **I** do in similar situations is, 1) connect my rig to a battery, and then 2) kill the main breaker to the house.

This permits me to know whether the noise is coming from my own home or from something external to it.

Most modern rigs will run at least the receiver from a 12 volt car battery. My borrowed FT-890 sure does.

If I find that the noise IS from my own residence, then battery-powering the receiver, while turning off the breakers one by one will often isolate the noise to a particular branch circuit.

If the noise turns out to be OUTSIDE the home, then more drastic measures are called for.

In my case here, I have a constant, 24/7/365 10 to 20 db over S-9 noise level on 80 meters which is NOT coming from my home.

Since the RFI is worse on the 40M antenna, which is closer to the house, I would still suspect there is something in your house causing RFI on the 110VAC wiring which is coupling to your 40M antenna. Other than UPSs and plasma TVs, some other likely culprits to check are halogen lights (sometimes used in kitchens) (the power converters can create nasty noise), flourescent lighting, grow lamp controllers, and light dimmers.

If you have a way to run your rig/receiver off a battery (or generator) for the short periods of time needed for RFI testing, you can start pulling breakers.

Good luck and keep us posted!

I noticed the inclusion of "UPS units" in your description. I have no personal experience with them, but of course they have inverters that might generate lots of power line RFI on their outputs. Don't know if that RF stuff radiates, or if it can get back into the power mains.

Have you considered adding a balun or isolator in the coax line, in the shack? I'm trying to think how RF would get from the power lines into the coax, other than as a current on the outside of the shield. A balun might break that path.

Regards,
Andy

Subject: [ham-antennas] Re: Coax vs RFI ?

Since the RFI is worse on the 40M antenna, which is closer to the house, I would still suspect there is something in your house causing RFI on the 110VAC wiring which is coupling to your 40M antenna. Other than UPSs and plasma TVs, some other likely culprits to check are halogen lights (sometimes used in kitchens) (the power converters can create nasty noise), flourescent lighting, grow lamp controllers, and light dimmers.

If you have a way to run your rig/receiver off a battery (or generator) for the short periods of time needed for RFI testing, you can start pulling breakers.

Good luck and keep us posted!

Very nice articles. I need to build a loop for 80M as I have some local noise that I cannot find that I have determined isn't in the house. Thanks for sharing!

Subject: Re: [ham-antennas] Coax vs RFI ?

Hi,
I have a short write up on removing RFI from my shack. Part I is here:
http://nk7z.net/rfi-now/
and Part II is here:
http://nk7z.net/rfi-now-house-cleaning/

Both cover how I removed most of my RFI from the shack...

I don't have a Plasma TV though... Good luck with that one...

33486. [ham-antennas] Coax vs RFI ?

Yahoo group: ham-antennas (2014)
Date: 2014-08-04 18:05:27 UTC
From: Geoff NW7GM
Topic: 33475 Message: 33486

Some UPSs create a 'modified sine wave' (using a PWM signal) instead of a true sine wave. This PWM signal usually isn't very clean and can create RFI.

I have quietly followed this thread with some surprise. I have an offset fed Dipole, for 10-80 meters, an end fed Dipole 6-80 meters

Is an "Offset dipole" the same as an Off-center Fed dipole?

Topic: 33475 Message: 33488

Thanks Andy: There is a Balun Designs 1113 used as the center insulator sealed properly etc except for the weep holes on the bottom of course. I have pretty much committed myself to leaving the coax where it is until the weekend whereas I can shut power down in the house and rule myself out. Do not have a spare 12 v battery, but have several dual battery UPS units with a 1250 va 850 watt capacity made by CyberPower and sold at Costco, LED display etc. So will report back on my progress after the weekend.

Subject: [ham-antennas] Re: End Fed Long wire Antennas

I have quietly followed this thread with some surprise. I have an offset fed Dipole, for 10-80 meters, an end fed Dipole 6-80 meters

Is an "Offset dipole" the same as an Off-center Fed dipole?

33490. Re: [ham-antennas] Coax vs RFI ?

Topic: 33475 Message: 33490

"There is a Balun Designs 1113 used as the center insulator ..."

The balun at the antenna is good, but how about one at the shack end? If there is significant RF being coupled onto the outside of the coax shield, it might follow its way down into the shack. Putting a balun or isolator there would break up that path, which *might* help. I don't really know fur sure, I'm kind of guessing. But that seems like the most likely way for RF to be getting in, if it is doing it by way of that part of the feedline.

Andy

Can you open the files in a text editor? If they are readable and contain rows of numbers and text, They could be MANNA-GAL or MININECPro input files. These are antenna analysis programs.

33500. Final(?) 4-el 2m portable Yagi results - files posted

Yahoo group: ham-antennas (2014)
Date: 2014-08-06 18:09:06 UTC
From: rob@...
Topic: 33500 Message: 33500

I've posted in the files section a K6RGI-Yagi folder which contains: the MMANA-GAL geometry file: photos of construction details; and both modeled and measured impedance etc. The objective was a Yagi whose elements would fit inside the boom for transport, and which could be set up quickly with no tools. The boom is 1-1/4" Schedule 40 PVC, and elements are 6mm Al rod. The feedpoint uses screw-type butt connectors soldered to thin brass strips. A piece of 1/4" acrylic is epoxied through the boom and the butt connectors are zip-tied and epoxied to the acrylic. (This design was shamelessly taken from M0UKD's). It's fed directly with LMR240, and there's a 5-coil ugly balun about 4' from the end cap of the boom. I tried various hairpin match options, but all made it worse. Reflector and directors slide through the boom and are clipped in place with small hairpin-type cotters. I optimized in MMANA-GAL for forward gain and wideband SWR match on 2m, with no priority given to F/B or directionality. Results look pretty good. The model says on UHF it's got a very strange pattern (max gain is at ~45 degree elevation) and a lousy SWR (3.6 at 435). The analyzer (Array Solutions) says the SWR actually isn't too bad on UHF. Haven't tested it much there yet.

Thoughts for the future - I may put the choke balun on the boom and add a female BNC at the tail of the boom so the feedline can be disconnect. Also, 1-1/4" PVC is overkill for the boom. 3/4" (maybe even 1/2") would likely be rigid enough, but might require a different feedpoint design. I'm hoping to do some real-world comparisons vs. Elks and Arrows using a field strength meter. I suspect they're

Thanks to Sigi, Geoff, Bill and others who've helped me through my mistakes on design!

10.7 MHz is the IF frequency for a FM radio.

You wouldn't need a broadcast radio station in the neighborhood to interfere with it, just a plain old pocket radio would suffice to create enough interference to cause you problems.,
This is the reason why the FAA does not allow you to carry on any ham radio FM handhelds onto a plane and the reason why they did not allow any electronic devices to be used while in flight for many years.

Today you can have practically anything except a transmitter.

33502. RE: [ham-antennas] MFJ Analizer

The alpha delta coax switch does not have enough separation to be able to use it to isolate a antenna analyzer from a transmitter.
I barely trust it between two radios on the same switch with the radios on either side of the switch.

33503. Antenna Switch Separation

Yahoo group: ham-antennas (2014)
Date: 2014-08-07 10:33:21 UTC
From: Scott Myers
Topic: 33503 Message: 33503

I've often wondered about separation on antenna switches. I need to buy a new 4 port switch. I need either a desktop type with ports out the back or perhaps panel mount.

Alpha-Delta switches are well built. Other than Alpha Delta, there's MFJ, Diamond and Jetstream, but I suspect they are worse than Alpha-Delta and they do not have all ports out the back. I've got an old round panel mount B & W in a box, but it turns very stiffly and I haven't tested to see if it is any good. I'd need a larger diameter knob on it at a minimum.

Then there are the Hofi switches which are at a "slightly" different price point.

Of course I could always go with a remote switch, like and Array solutions Rat-Pack, and use it in the shack getting rid of the coax coming to the operation position.

Anyone done any testing on isolation on any of these witches?

Scott AC0DE

From: WVØH
Topic: 33503 Message: 33505

Way back when I tested an MFJ, Alpha Delta, and an old B&W, the highest isolation from port to port was had in the opposite ends of the AD, then the MFJ, then the B&W. The highest isolation was in the neighborhood of 50-60 dB in the AD down to 20 dB in the B&W. So I use the AD on my VHF/UHF antennas, the MFJ on my 6m antennas, the B&W on my HF antennas.

That's a good point.

On the other hand, it is my understanding that the MFJ 259/269 have a
wideband detector, so it doesn't need to be tuned to a band close to the
interfering signal, to be affected by it. So this might not explain why
Richard's MFJ-259B misbehaved only on 30 meters.

(Also if I remember right, some of his 259B's *calculations* seemed to be
off ... as in, the numbers for R, X, and SWR were not consistent with one
another. That doesn't make sense; seems more like a firmware error. Beats
me why it would be band-specific.)

"This is the reason why the FAA does not allow you to carry on any ham
radio FM handhelds onto a plane ..."

Indeed, they didn't allow even radio receivers (i.e. Walkman) to be turned
on, for this reason. Too much concern about the radiated IF at 10.7 MHz
and 455 kHz, and the latter is right in the middle of the aeronautical
beacon frequencies.

Regards,
Andy

33508. Re: [ham-antennas] MFJ Analizer

Yahoo group: ham-antennas (2014)

From: Mel Farrer
Topic: 33447 Message: 33508

One thing I might add. I have built up a set of impedance references. That is 25, 37.5, 50, 75 and 100 ohm resistive terminations. I also made up a tee where I can connect a reactance in parallel with the load. Again at the frequencies of interest, like 10 MHz. Not difficult to calculate and build up, but sure puts a cap on whether or not the analyzer is in calibration and giving me the appropriate data. Just a thought. No more questionable readings.

As a side note, last year I started using the FG-01 analyzer and the first one did not agree with the terminations with reactance, resistive terminations were fine. I put the analyzer into my HP8920 and found the 2nd harmonic was only down 6 dB. Sent it back and all is well now. Without the reactive termination, and the checking of the calibration, I would have had REALLY bad data.

I have checked several MFJ 259 units and the second is always >35 dB below the fundamental.

Mel, K6KBE

Gentlemen , I am still confused about my strange readings with my MFJ-259B on my 10MHz vertical. I was hoping someone else would have a similar problem at 10MHz.

I cannot afford to buy a different analyzer to check this one antenna, unless it was the XYL’s idea, hihi.

I have no other radio turned on when checking.

There is no other houses within a half mile of me

Low power, single vertical antenna FM station 12 miles away.

My Kenwood TS-590 is limited to ham bands only and I don’t want to open it.

With the small spread of less than 50 KHz it looks about the same.

It is good enough as it is today but it seem strange how great it was as a homemade 7Mhz antenna and shorting up the elements you can’t make it as good on 10Mhz

It is easy to confuse a old man, I am proof of that.

Rich, Kd0zz

I agree that wire is pretty much wire. I have roles of different kinds from garage sales yard sales and estate sales bought for less than scrap price. My 574 foot loop has 500 feet of stranded wire from an electronic dog fence and 74 feet of solid wire from something. both are insulated and tied together (36K20 Army style). It goes up and down a few times a year, for the last 6 or 7 years, for field day camping and such but spends most of its time on a spool where it is now. I've stopped worrying about it breaking from getting work hard. I think I noticed it getting a little bit work hard but I'm not sure because as I near 60 my steering wheel and wrenches are getting work hard too. I try to stick with copper wire because it is harder for me to guestimate the velocity factor difference in aluminum and stainless steel. I think what I'm trying to say here is don't sweat the small stuff you can have a lot of antenna for very little money If you're willing to put it up and down a few times to get it zeroed in. My total cost for the loop with 4:1 balun is under $7 (that kinda' feels like an arm but at least it's not an arm and a leg). And life sure got a lot easier with the MFJ 259. Abe

The Alpha Delta coax switches have >60 dB isolation from port to port. All "unselected" positions are internally grounded.

Subject: RE: [ham-antennas] MFJ Analizer

The alpha delta coax switch does not have enough separation to be able to use it to isolate a antenna analyzer from a transmitter.
I barely trust it between two radios on the same switch with the radios on either side of the switch.

Gentlemen , I am still confused about my strange readings with my MFJ-259B on my 10MHz vertical. I was hoping someone else would have a similar problem at 10MHz.

I cannot afford to buy a different analyzer to check this one antenna, unless it was the XYL’s idea, hihi.

I have no other radio turned on when checking.

There is no other houses within a half mile of me

Low power, single vertical antenna FM station 12 miles away.

My Kenwood TS-590 is limited to ham bands only and I don’t want to open it.

With the small spread of less than 50 KHz it looks about the same.

It is good enough as it is today but it seem strange how great it was as a homemade 7Mhz antenna and shorting up the elements you can’t make it as good on 10Mhz

It is easy to confuse a old man, I am proof of that.

Richard, seems to me you are near 10 Mhz WWV and with a 10 Mhz antenna you are possibly getting overload from them. Just a thought out of the box.

Rich,

Since measuring 10MHz is at the near end stop of the two ranges the analyzer has, maybe your unit is in need of calibration or is defective. When getting close to one of those ranges, my 269 acts "weird" when going below 10Mhz.

Just a thought.

DUN-NO but he can check it with a calibrated S meter or such. Also any high
power Short wave station close by could contribute. A spectrum analyzer
would be nice to see what is putting a signal into his location.
does appear to be either malfunction of equipment or over load.
I used to have trouble with AM and FM stations years ago in Florida. Had to
add filters to all my receivers and station monitor.
Had interfering signal on repeater also and found it was rectification in
rusted guy cables mixing local FM and Police transmitter. Heck to locate
due to intermittant interruption. So RFI can come from anywhere.

Amen! The FCC warned me not to work for a specific FM station that they were about to descend on.. Oddities with the transmitter and corrosion on guy wires resulted in a spur from their tower (not necessarily their transmitter) in the aircraft band. Multiple other stations in the immediate vicinity, and the fact that they were within 2 miles of the approach path made that a "high priority fix" to say the least.. Apparently the chief field engineer in Tampa at the time had asked the station to clean up.. and they had not in a month or two, so he was getting ready to make mincemeat of 1) their budget and 2) their CE's license....

Aehem ... why is the sark100/mini60 not available ?!?

Just buy it online and a few days later it will arrive

Nothing difficult with that

....

Or build your own (pcb and firmware are available online ... see below)

But I am guessing that buying a complete device is a lot easier

Just look in evilbay

http://www.ebay.com/sch/i.html?_from=R40&_sacat=0&_nkw=sark100&_sop=15

Or on aliexpress

http://www.aliexpress.com/w/wholesale-sark100.html?SearchText=sark100&CatId=0&shipCountry=de&initiative_id=SB_20140807122150&SortType=price_asc&filterCat=15370308,15370305,153712&groupsort=1

.....

Or ...

All show the sark100 for about 90-100 bucks and the mini60 for around 120-150 bucks

Mini60 is nearly the same thingy but it is smaller, has a built-in Bluetooth and build-in rechargeable battery pack

Sark100 has no Bluetooth but that can be added (bt module for around 5 bucks) ...

So its on your side to think what model you would prefer

... if you like homebrewing things

http://www.ea4frb.eu/antenna-analyzers/sark100/Archive

here you find ALL building info for that analyzer, pcb design, firmware ... etc.

...

33521. Re: [ham-antennas] MFJ Analizer

Yahoo group: ham-antennas (2014)
Date: 2014-08-07 20:45:15 UTC
From: Andy
Topic: 33447 Message: 33521

My understanding about the MFJ 259/269 analyzers (designed by Tom W8JI by the way) is that they have broadband detectors. Thus, if it is being affected by strong RFI, it would happen irrespective of the band or frequency setting. The fact that it's close in frequency to a 10KW radio station hundreds of miles away, should be irrelevant.

What can mess them up (and I think this was mentioned just recently), is the waveform purity, i.e., harmonic content of the oscillator inside the 259/269. Its oscillator runs at a somewhat high power level ... hence draining the batteries faster ... in order to get the low harmonic content it needs.

However, if for some reason its oscillator's harmonic or spurious level shot up in the vicinity of 10 MHz, that could explain why Rich couldn't get the SWR to appear low enough only on that band. It would be measuring the reflection coefficient at 10 MHz AND other frequencies simultaneously.

10 MHz appears on two of the MFJ-259B's overlapping ranges: at the upper end of the 4-10 range where C is minimum, and at the bottom end of the 10-27 range where C is maximum. It is unlikely but possible that the oscillator is running out of steam at the far end of one of those ranges, and generating either a harmonic, or a spurious signal of some sort.

It might be useful for Rich to repeat his measurements with his '259B set to both the 4-10 range and the 10-27 range, and see how they compare.

But the thing that really puzzles me is why he was getting good readings for R+jX and simultaneous not-so-good readings for SWR. Like I say, that seems to me more like a miscalculation by the '259B's CPU, than anything of an analog nature. Weird.

Regards,
Andy

33522. Re: [ham-antennas] Stranded Copper Wire for Transmitting

Yahoo group: ham-antennas (2014)
Date: 2014-08-07 23:06:18 UTC
From: Andy
Topic: 33450 Message: 33522

I think we all agree that antennas can work no matter how little theory goes into them. Any wire can radiate. Someone gave the example of oldtimers using nothing more than the ARRL books; but folks before that didn't even have those books to go by. They strung up some wire, any old wire they could find, and lo, most of them worked. Good old tube rigs.

Just the same, it doesn't hurt for some people to look at the finer points of antenna theory, at least so we can see IF it makes any difference.

Someone wrote: "they (solid cables) also would not conduct the amps the stranded cables do".

I disagree. At DC and very LF, equal copper cross-section conducts exactly the same, whether stranded or solid. The stranded cable actually needs to be a little fatter, to get the same cross-section and conduct the same as solid.

Have you seen those solid bus wires at electrical substations? Yup, they work pretty darn well.

Stranded wire may be the preferred choice for battery and welding cables, but it's because it handles easier. Solid of the same size conducts just as many amps.

The issue of AC resistance and skin effect is an interesting one. John suggested that stranded is slightly superior because it has more surface area. That's partly correct, but on the other hand, the current tends to congregate or gather on the outermost surfaces ... the ridges that stick out the furthest, with less current in the valleys between them. The result is a less efficient utilization of available surface area, and actually more AC resistance than solid wire with its perfectly uniform surface. It is frequency dependent, and just like the difference between solid and stranded, mostly not noticeable anyway.

Litz wire is the exception. Litz wire is a specially made stranded wire where each tiny strand is individually insulated, and the twist pattern is carefully controlled so that each strand spends an equal amount of time on the outside of the bundle. This prevents the current from congregating on the ridges. The result is an equal current distribution and a true reduction in AC resistance. But this works only up to a couple MHz. (FYI - NIST uses a monster Litz wire in the antenna tuning unit for WWVB.)

Regards,
Andy

Beaten to death, but I can make one contribution.

Stranded surely handles better in welding but it is used on auto and marine batteries because of the vibrating environment - not unlike a wire antenna in wind.

Crimped, not soldered, stranded cables are best in a pounding hull because everything moves. Given a choice, I'd opt for stranded in the wind for the same reason.

Tom

Wonder if plugging one of them into a spectrum analyzer might offer some insight?

Perhaps the offending instrument which started this thread, check on both frequency range switch settings.

Rich,

Since measuring 10MHz is at the near end stop of the two ranges the analyzer has, maybe your unit is in need of calibration or is defective. When getting close to one of those ranges, my 269 acts "weird" when going below 10Mhz.

Just a thought.

Gentlemen , I am still confused about my strange readings with my MFJ-259B on my 10MHz vertical. I was hoping someone else would have a similar problem at 10MHz.

I cannot afford to buy a different analyzer to check this one antenna, unless it was the XYL’s idea, hihi.

I have no other radio turned on when checking.

There is no other houses within a half mile of me

Low power, single vertical antenna FM station 12 miles away.

My Kenwood TS-590 is limited to ham bands only and I don’t want to open it.

With the small spread of less than 50 KHz it looks about the same.

It is good enough as it is today but it seem strange how great it was as a homemade 7Mhz antenna and shorting up the elements you can’t make it as good on 10Mhz

It is easy to confuse a old man, I am proof of that.

Rich, Kd0zz

Topic: 33447 Message: 33529

Not the IFs...that doesn't radiate...or else it would not part 15..

It's the Local Oscillator on FM radios....they are high side injection....so radios tuned 97.3 or higher are radiating the LO into the aero band...So that could throw off VOR reception and interfere with voice channels as well....

Ham gear is not allowed because the prohibition covers all radiating equipment (you can carry on, you just cannot legally use it while in flight)....IF you get permission from the carrier on a commercial flight (NOT the pilot...he is not the carrier), you can operate legally (good luck)....On private planes, permission of the pilot is all that you need.

BTW JVC Kenwood (owner of Panasonic) has been testing under an experimental license (WF2XLF) recently in test aircraft at certain airports...as a Society of Broadcast Engineers Frequency Coordinator, I was contacted some time ago about testing going on this week at Chennault airport (former AF Base) in Lake Charles, La (to make sure no Remote Pickups or TV ENG was interferred with)...it involves mostly UHF and 2GHz on this test at LCH at up to 15w ERP. They are checking Panasonic Avionics Global Communications Suite (“GCS”) featuring the“eXConnect” Ku-band earth stations aboard aircraft (“ESAA”) system to provide broadband connectivity onboard aircraft in flight.

However, the FCC will never allow FM radios or high power RF devices which could?interfere?with the fly by wire systems or comm/navigation.

Chris
WB5ITT

==========

"This is the reason why the FAA does not allow you to carry on any ham radio FM handhelds onto a plane ..."

Indeed, they didn't allow even radio receivers (i.e. Walkman) to be turned on, for this reason. Too much concern about the radiated IF at 10.7 MHz and 455 kHz, and the latter is right in the middle of the aeronautical beacon frequencies.

Regards,
Andy

Hi

I am just getting back into HF after selling my house a the 60 ft. hd tower and TH6Dxx antenna duet health. I installed a MFJ balcony antenna that uses loading coil and opposite end about 10 ' away a 75m. hamstick. I can not get a good ground plane. First I used the metal railing and no luck Then auto tuner with 6 lengths of 1/4 wave wire and swr is still way out of range. The rig is a Yaesu FT-897d. I thought about taking my ATAS-120 and mounting it on my railing but it would be too dangerous as I am 8 stories up. Any help would be so appreciated.

Wayne,

I also bought the MFJ balcony antenna and had little luck with it. However, the bracket that it has is the support for my current end fed wire. I put a wooden pole in the bracket so that the long wire is about 5-6 ft from the side of the building. This helps prevent courious people from below grabbing the wire. My wire is about 66.5 ft so might be a bit long for your 6th floor (I am on 15th) but I'm sure a shorter wire could be tuned. I also have a counterpoise (3 different length wires). Look as my QRZ.com page for a picture.

I know of the MFJ balcony mount, but I don't own one. What frequency
are you operating on?
It seem to me adding a loading coil to a 80 meter HAM stick would put it
on 160 meters and a 140 foot "tiger tail" would be required. (14 stories)
Have you tried a 10 meter HAM stick on 15 or 20 meters?
Tell us more of your operating plans.

The "photon" and the E and H fields are the same thing, looked at in different ways (particle vs. wave). The photon is the quantum of the electromagnetic field.

There is thought to be no aether.

I was looking over the MFJ 1625 this morning, The first thing I don’t like is you mount the antenna on the back of the tuner.

Can you mount the antenna on the balcony and use the tuner in the house?

My second thought was to run a wire from the frame of the antenna to the Grounded (Green) screw or pin of a receptacle to give you a ground grid.

What about installing an autotuner (with "random wire") ... installed at balcony ... railing and maybe a few wires added as "counterpoise" (something the tuner can work against) ...

Wire thrown in the next available tree (we call that a potato antenna ... grin) ... (add some rope and an insulator at the end)

Should work MUCH better then any mobile or "balcony" antenna

And it is nearly invisible if installed high enough (8 stories is high enough for that!)

Like any vertical installed at the beach it should work well

I modelled a similar thing in mmana for 40m ... 7.5m vertical with 2 radials
and 2 top wires ... fed at the base (so asymmetrical feeding!)

Impedance is around 50 ohms (no tuner needed ... no lossy coils or caps at
the feeding point)

Did not build in real (yet) but the results seems promising

Hi sigi,

I've been looking at the k2kw team antenna pages and it looks a good set up. I have a 12m spiderbeam pole. Was thinking if doing one for 40m 1/4 radiator with two raised 1/4 radials. But I've not got the modelling software to see what it's like. If I uses 12m mast then the feedpoint will be up about 2m.

Hi Billy

Mmana is freeware so it is easy ... just download and install it

http://hamsoft.ca/pages/mmana-gal.php

And then I can send you a model from my version (and it is also easy to make own modelling with it)

Mmana has a nice graphical editor built-in

If you ever used ANY paint software you will know how to draw your own antenna models (click at beginning of wire, hold mouse button and draw the line to the end ... then reelease button ... easy)

This antenna concept strikes a lot of similar thinking of the C off center fed dipole???

33543. Antenna turns counter

Yahoo group: ham-antennas (2014)
Date: 2014-08-08 22:10:53 UTC
From: farrerfolks@...
Topic: 33543 Message: 33543

I got tired of looking at the automatic, manual, etc., screwdriver controllers >>$100. Most of us started with just a up down toggle switch. What all that is needed now is to count turns.

Here is a little afternoon project for a self powered, up down LCD display counter. Li coin battery <5 uA all day long. Total parts count without the terminal strip, box, and wiring, "4". A diode to sense motor direction, relay to instruct the counter to change directions, 2430-T battery, and the Trumeter 7400AS 8 digit LCD counter assembly. The bench picture shows the basic parts save the relay, I used a toggle switch. I set it up on my Hi-Q antenna and it works great. I mounted the box in front of the Odometer. Now I do need to calibrate the counts with the bands. Make a cheat card and I am on my way. Thought you might like to see what I did this afternoon.

Thanks Ken but not sure it is just a MFJ problem. I think there is a antenna problem I am not seeing, been building antennas for 35years so my eyes might have gone bad. When it was a 40M (7MHz) antenna things agreed perfect with the tape measure and SWR meter, 1.2:1. I am not too close to house or other antenna and no power lines around, coax checked and double checked. I trimmed the raised radials and adjusted the vertical element to 23.1 ft , 30M (10MHz) length, SWR is 2.5:1 at 10.1MHz, the low SWR point is 1.5:1 at 9MHz but all elements are at 23ft not 26ft. I will let it rest for a few days and start over.

From: Richard Schmuke
Topic: 33447 Message: 33547

Good I idea mike to check it out on harmonic. Ran into a snag doing that. Checking at different harmonic frequencies the antenna then needs a 2:1 balun at the base and my 2:1 is too big to attach at the feed point. SO-239 too close to wood mast. I thought adding coax jumper might mess things up. I could use a 75ohm coax matching section but then would not be able the check different frequencies. I have used the 2:1 balun with dipoles having 3, quarter wave lengths per side and it worked fine. Checking at the shack end I do get slightly better reading on some multiples of 10MHz, others on multiples of 9MHz. I still can't understand why bad SWR at 23ft elements. High SWR with radio and separate SWR meter as well as the MFJ-259.

The 20M antenna will be rebuilt, it must be a problem at the feed point. Original picture was for another antenna, wrap around copper was removed for the 40M and 30M verticals.

http://s1102.photobucket.com/user/KD0ZZ/media/Multi%20Band%20Vert/MBVert011_zps2248882b.jpg.html

The assembly inspector will be fired for lack of attention, no special treats for 72 hours.

http://s1102.photobucket.com/user/KD0ZZ/media/Multi%20Band%20Vert/MBVert005_zps78008c01.jpg.html

I ran a quick check on the MFJ-259B by making a quick & dirty dipole with a BNC twin binding post fitting, some silver plated 18 ga, center conductor end held by a string to a 8 ft step ladder the shield end to a lawn chair. Eye balled at 23’1” and MFJ said SWR was 1.3:1 so it can work at 10MHz. Got to be a glitch in the antenna. All parts covered now by non-corrosive RTV so I will take down, clean up and start over.

From: Mel Farrer
Topic: 33447 Message: 33552

The non corrosive RTV will not cause a RF problem if allowed to cure 24 hours. The Acidic RTV is TERRIBLE. It is conductive during and after curing if ANY moisture is around.

Mike I agree on that one.

I use to repair microwave ovens and admiral IIRC had a Sealed glass tray in
the bottom
that if it broke it was like replacing window glass.

But I do remember that you had to use a special RTV? silicone to seal it in
with and then
let it set for 24 hours before operating the oven for 15 minutes with a
quart water load.
(This was about 40 years ago).
I do remember that instructions said something about an certain smell but
not what for it
to be right silicon to use.

So it is possible the silicone is upsetting the match.

From: Mel Farrer
Topic: 33447 Message: 33555

Mike the answer is yes. Consider this. The RTV is a liquid with a certain level of conductivity as the material cures out. During that time, IF you put two pieces together in a microwave they will flash. Wait 24 hours and, NO flash. Simply follow the directions of use. Until fully cured. This probably does not answer the original question. I brought it up as a precautionary thought.

33556. Materials used in RF fields

Yahoo group: ham-antennas (2014)
Date: 2014-08-09 22:57:18 UTC
From: farrerfolks@...
Topic: 33556 Message: 33556

We have gone around the issue of materials to use and those not to use. My background is in HIGH RF environments. That is RF is the milliwatts to the Megawatts. From broadcast to 24 GHz. The issue of what to use for a passive material is a extremely difficult subject. Materials at low frequencies are not acceptable at low VHF due to intrinsic loss. Called among other things, loss tangent. OK. For our use, at HF, here are some guide lines.

Many materials have varied RF loss characteristics as you go up in frequency. Stuff at 3 MHz and below are fine up to a point where the loss tangent, susceptibility to RF, gets to the point of causing power to be dissipated in the material.

Same with any formulated adhesives. Especially during the curing process. I have not seen any manufacturer that is willing to put forth any data on the RF characteristics during the curing process. For good reason, too many variables.

So rule of thumb. Use known materials and formulations. Relax, let the process work. Then get to it.

If you want to go further on materials, let me know, I have lot of experience in High Power RF materials.

IMHO

Mel, K6KBE

33557. RE: [ham-antennas] MFJ Analizer

The smell is a vinegar smell, actually acetic acid from original or now called type I (one), newer RTV type II (two) is non corrosive. It all worked fine months ago as a 40M antenna when first made.

Good I idea mike to check it out on harmonic. Ran into a snag doing that. Checking at different harmonic frequencies the antenna then needs a 2:1 balun at the base and my 2:1 is too big to attach at the feed point. SO-239 too close to wood mast. I thought adding coax jumper might mess things up. I could use a 75ohm coax matching section but then would not be able the check different frequencies. I have used the 2:1 balun with dipoles having 3, quarter wave lengths per side and it worked fine. Checking at the shack end I do get slightly better reading on some multiples of 10MHz, others on multiples of 9MHz. I still can't understand why bad SWR at 23ft elements. High SWR with radio and separate SWR meter as well as the MFJ-259.

33558. uploading sound files to this forum

Yahoo group: ham-antennas (2014)
Date: 2014-08-10 03:17:52 UTC
From: p_chap@...
Topic: 33558 Message: 33558

Could someone advise me on how to upload any format or any codec to this forum as it would represent my RFI demo, no need for video, audio is fine.

Any time you plan a weekend to chase down RFI and have pretty much free reign to unplug everything and turn off the main, the RFI ain't gonna happen. It varies in the crackle a little bit although not much, signal wise constant s9 plus 10 dead on. After a week long 24/7 S9+10db RFI. and it has been so steady, I have started to look at things that are common to find the solution.

The first thing I look at is the guy down the street. I can both expect, predict, and even depend on him being drunk and half talking, half singing, each day and every day. I would not exactly call it anything from the Sound of Music nor a classic from Pavarotti, who is still spinning in his resting place over Freddy Mercury and Montserrat Caballé. Today, I have not heard him, and I have not heard the RFI. Is this the possible source? Obviously he is full of foul emissions that could very well be the source. When walking in my yard I have heard many foul emissions from this neanderthal, even though he does not own a radio. I have not heard him since last night when the RFI stopped. I do have a second thought. The drunk down the street was buds with the drunk that moved that blew up his pickup truck, so maybe there was a plasma deal done that helps to connect the dots.

My second issue is my wife. Not long after getting home yesterday, she put on some weird tin foil type dress, and shortly thereafter I noticed there was no RFI in the radio. I had no choice and I could not take a chance. I quickly wrapped her in amalgamated tape and put one end of the auto jumper cables on the dress and she is currently tied to a totem pole in the yard with the other end of the jumper cables going to the ground rod. At this point, I have not decided whether she will be traveling or not this week. It will be based on results of the other outside factors.

My third concern is the pooch, the dog.....unlike all others that you see in comics with thought balloons that display perfect English., she is quite different. The only things I ever see in her thought balloons are one's and zero's and lately I have gotten quite concerned as there are pauses and at times I get numbers of zero through nine and letters of A through F. When it gets to that level I feel it is a scary situation and possible source of the problem.

Well I said I would report back with a progress report and like it or not sometimes you can not fix something without the broken symptoms.

Surely when creating filler, you have to come up with a bit that is not quite true.....in order to help you differentiate, the only stories I have mentioned here that are true are the ones about the neighbor, the wife, and the dog.

Please do not forget to answer my question on sound files. Regarding the RFI, you have to have failure to find success.....hope the snarky humor gave you a laugh or two

I like your so 239 mount :-)

Looks nice

Dg9bfc

Sigi

> -----Ursprüngliche Nachricht-----

Thanks Sigi , for others , a quick and easy SO-239 mount can be made with a small section of alum angle and a few holes . This lets me attach my coax to the treated 4x4 pole. Radial attachment at the second picture. Note: this was from a multi band vertical antenna that did not work, too much interaction or was this the start of the RTV problem? No matter next week it will be remade.

Hi Rich, I have been following this thread and finally saw the photos with the pressure treated lumber and the connectors. Pressure treated lumber is conductive because of the metal salts used to retard rot. It will usually remain so as long as there is any moisture in the lumber, and in some cases it continues to be just slightly more conductive than Mylar for its useful life.
Not sure if that has anything to do with your issue, but back in my wood products days we issued cautions about using pressure treated lumber around electrical and RF applications unless steps were take to insulate conductors from the lumber.

You provide another reason for a complete rebuild. My original was to insulate from the post with a PVC sleeve but I took the easy way out and bored a hole down the center of the 4x4 for a slip fit to the aluminum tube.. The lower 6” of tubing is double walled and then a SS #10 machine bolt conducts to the outside. Plenty of opportunity for problems you describe. One question still remains, how did it work OK as a 40M (7MHz) antenna? The MFJ provided good readings with my quick and dirty dipole yesterday so it can operate on 10MHz with no problem thus giving more creditability to you idea for a source to the problem.

Any one else have a problem with treated wood??

Randy, using a good Fluke meter I get 10MOhm’s from my vertical to a clamping bolt thru the 4x4 & 2x6’s but then this is at DC. Thinking back to when I tried to use this post as a “fan type” vertical all the readings on the higher band could not be tuned in. Time for a rebuild with insulation.

/*snip*/

You could always stick a 30' telescoping fiberglass pole out the
window with a 43' supple wire up through the center with the excess
hanging down with a good antenna tuner for all HF bands. You might need
to drop a 43' tiger-tail down the side of the building as a
counterpoise, if a ground wire to the radiator or electrical ground
system isn't helpful. (when not in use the pole can be pulled in and
collapsed into a ~4' pole and a coil of wire, any tiger tail retracted)

33568. Portable tripods question

Yahoo group: ham-antennas (2014)
Date: 2014-08-10 19:19:28 UTC
From: Keith Heimbold
Topic: 33568 Message: 33568

I am about to move into a house with a large backyard with no significant sized trees (just a couple fruit trees) and no ability to put up or nail anything to the house or Dig holes in the ground.

I was curious about using a tripod like the MFJ 1919 for a HF vertical antenna (like a 5BTV) or a small 6m beam (two or three element). Would the tripod provide enough support for either antenna. Just curious. I would probably take it down after each use so my landlord won't be bothered by it. I would use a radials for the vertical like the stub tuned ones I made long ago for the butternut HF6V.

Thanks,

Keith

Date: 2014-08-11 18:47:19 UTC
From: ad_prasad@...
Topic: 33573 Message: 33573

Group,

I am looking to build a G5RV because I have the space to accommodate the 102 ft length. I looked at many designs on Internet. All give a horizontal 51 ft long wire length on each half side. However I did not see any reference to the type of wire - i.e., should it be bare or insulated. I think the velocity factor may play a role and make it necessary to reduce the length if insulated. Can someone with experience answer me please? Or, am I looking at an irrelevant issue?

Thank you

Sure. I will have a proper ladder line as a feeder. I will have a 1:1 balun at the end of the ladder line. I will then use a good quality coax from the balun to the rig. My question is what type of wire should I use at 51 feet length? Bare or insulated? If insulated I thought the velocity factor would play a role. Won't it?

Thanks

A slight difference but nothing to over concern your self with. Solid copper is fine I prefer insulated but won't worry about it effecting the antenna that much. I've made a half size with the sizes on line with insulated wire. Didn't make any difference.

I would see what the performance is with the radials, and then disconnect
the radials and see if the performance is still good, (still have radials)
and if the performance is a little off, or a large amount off, then you
might check the radials, and an ohmeter that's
sensitive might show some resistance.

As long as there us an electrical connection I would image they would be fine. You could get a multi-meter and dig up the end of the radial to ensure the earth of the connector has conductivity with the end of the radial. If your meter buzzes then you know that the connection is good all the way. How long have they been buried for? I would image they would be fine but you could also add some new ones to make sure. I can remember reading somewhere that a ground mounted vertical really needs around 120 radials for best performance. An raised vertical needs a lot less. If you have the space you can always add some more ;)

33587. Antenna spacing help needed

Yahoo group: ham-antennas (2014)
Date: 2014-08-12 13:45:41 UTC
From: myfamilydotcom@...
Topic: 33587 Message: 33587

My current antenna system includes a 32-foot self-support tower supporting an HF beam & a VHF beam. The tower, antennas and rotor were all second-hand projects that I obtained and repaired/rebult.

I have a new 6 meter beam that I am thinking of adding to this tower.

My question is about antenna spacing...

My tower supports the Mosely TA-33-M-WARC beam just above the thrust bearing (at the 32 foot level), and the vertically-mounted VHF Cushcraft A148-10S 5.5 feet above the HF beam. At the time I designed this layout I asked both Cushcraft and Mosely support for advice on the spacing and to be honest neither company gave me much well-thought-out advice. Our tower-work season here is so short I really cannot afford the time to put things up and take them down over and over again to test as much as I'd like to, but I like the way these antennas currently work so I think I may have sufficient spacing. Since the HF beam is horizontal and the VHF beam is vertical I suspect that there may not be much interaction at all between them as currently built.

Here's the question:

While vacationing in Maine last week I bought a used Cushcraft A503S which is a 3-element 6 meter beam. If possible I'd like to lengthen my mast at the tower and place the new 6-meter beam horizontally between the HF beam and the VHF beam. What I really would like to know is how much spacing I really need to do that so that these antennas don't get messed up, since I won't have time to raise and lower it over and over again and I don't want to go all winter with a messed up HF or VHF antenna system.

The rotor and current antenna loads are well below their specified load ratings, and the Cushcraft A503S won't push me over the limits if extension heights are reasonable.

If this were yours, what spacing would you use? Are there experts who have plenty of practical experience you could refere this to? Possibly the old-timers have rules of thumb backed up by theory and a lot of practical experience that I don't have.

Review:

Top VHF beam mounted vertically is a Cushcraft A148-10S (12 foot long boom, 10-element) Middle 5 Meter beam is Cushcraft A503S mounted horizontally (6 foot long, 3 element) Bottom Mosely TA-33 M-WARC HF beam mounted horizontally (14 Foot boom, 4 element, covering 10, 12, 15, 17 and 20 metres) starting atthe 32 Foot point Rotor is Alliance HD-73-1 mounted inside the tower about 3 feet below the tower top where there is a thrust bearing.
Thanks

Kevin

There's a very good pragmatic two part article by Barry Booth in QEX this year that deals with location of loading coils and the effect on verticals.

Not sure, but I think Cebik did a section in his works on the subject of verticals and eff with respect to coil location.. Will see if I can find it.

A quick antenna tip: For any newly installed antenna system, after it is tuned to your favorite frequency (frequencies for a multiband), check and write down the swr. Comparing new readings with your originals will let you know if anything has changed.

Hi Jay,As others have mentioned, your radials are OK. The only time I've seen a problem with deteriorating radials is when made from Aluminum wire and put into acidic soil; they disappear in about two years. Copper, especially insulated copper, should have no problems for many many years unless they get dug up or cut. AM radio stations have many very long radials made from copper; they are good for the life of the station. Keep a record of your antenna's SWR in a log; check around the same time of year on each band. If you check it seasonally, there will be some differences between Winter, Spring, Summer, etc. Depends on the vegetation and rainfall.I have over 50 insulated copper wire radials for my vertical antenna; half are buried and the other half were stapled to the ground. Neither have given me a problem.Now, how to check them if absolutely needed. First, we know they are all shorted together at the radial plate. Use a metal detector to located the wires and find the far ends. Dig just the ends up and put an ohm meter between adjacent wire ends. It should show a couple of ohms caused by the wire, but any low reading means the wires are OK. I've found that copper wires in the ground can be hard to find unless a decent detector is used. Contact a local detector club for help, if needed.73, Jimmie, K9JFK

if you can find a signal.. see what it looks like, then disconnect the radials & re check it.. but Like other say, if the swr is good. & you haven't noticed any degradation in signal.. they are prob fine.

Remember, all 1/4 wl vertical antennas exhibit a better (less
reflected power) SWR without radials than they do with good radials.
(50 Ohms verses 37 Ohms because dirt becomes part of the system)

Observing the receive signal levels depends on setting the receiver's
AGC off and the RF gain at a fixed value.

I used to service a local 5000W AM station. We hired Robinson Tower Company from NC to move the antenna system to a better location. Mr. Stanley Robinson brought with him a plow which he had modified to plow wire radials into the ground. We hired a local farmer and his tractor to do the dirt work. Can't remember if it was 12 ga. or 10 ga. wire but we plowed in about seven (7) miles of copper taking each of the 200 or so radials to the property line. The installation put out a pretty good signal on 1290 KHz.

Jay,

If you used 14 and 12 gauge copper THHN, the radial field will outlive you! No need to check it. The PVC insulation will stop it from deteriorating, but and even bare copper holds up well in the ground. And you used quite heavy wire, so it is mechanically strong as well. The only way the radials are going to break is if you have a herd of cattle or horses trampling around the radial field with their hooves. Or maybe a kid bouncing on a pogo stick. Short of that, they're fine.

You do need to check the connection end from time to time making sure that is good. Mechanical connections do oxidize. It's the only place you need to inspect every year or so. It's a good idea to goop up the connections with something to keep the weather off; paint, RTV, coax seal, etc. And of course the coax shield's connection path to the radial system needs checked as well.

Someone mentioned 120 radials being the point of "best performance". Well sure... if you want to spend the money, but unnecessary. I think commercials stations have to have 150. The fact of the matter is that 64 radials a bit longer than your radiator is tall is the real point of diminishing returns. Above 64 radials (which gets you to about 90% efficiency), you make just single percent point gains. Definitely not worth the money, as the stations at the other end won't be able to tell the difference as you are talking fractions of an S-unit.

A lot to read on the subject from N6LF, who many manufacturers and the ARRL rely on for radial info.

Subject: [ham-antennas] Radial performance

How can you determine the performance of your radial field. I have 32 radials somewhere between 20 and 40 Ft surrounding my DXE 43ft vertical. No UnUn, an Icon AH4 at the base remotely controlled. I can see them connected securely to the radial plate and disappear under the lawn. All the radials are #14 or #12 thhn wire. They've been there about 5 years. My concern is are they still there or have they deteriorated.

How can you tell ? The antenna seems to perform OK but have no way to gauge it.

From: Kenneth G. Gordon
Topic: 33596 Message: 33596

Gents:

I have run into a problem here which, at least to me and a couple of other folks, we regard as "serious".

I am one of several people who are trying to make reliable contact for EMCOMMS purposes with a ham in Alaska, "Ed" Trump AL7N in Fairbanks, on 14115 CW.

His antenna is a 1.5 wavelength vee-beam pointed in "our" direction, and his power output is around 50 watts.

I have been having a very difficult time making reliable CW contact with him, despite running 600 watts output to my 55' vertical.

Within minutes of my being able to just barely hear him, and vice-versa, I make very reliable contact with Jerry KL7EDK on 14064 kHz, who is also in Fairbanks, via PACTOR, when I am running 50 watts, and Jerry is running around 30 watts output. Jerry's signal is WAAAAAAY above my noise level, whereas Ed's is at or below the noise level. Jerry's antenna is a compromise of some sort: a dipole I believe.

What I would like to request is to have someone here who knows how to do it to model Ed's antenna to see what its radiation pattern might be.

I hope to have all the necessary parameters later today.

I suspect his signal is bouncing over mine, and vice versa.

Any suggestions you folks might have would be very sincerely appreciated.

Ken W7EKB

Ken, yes, I would be glad to model it for you as I am sure others will volunteer. I couple of thoughts, Make sure you have the dimension of the open end, height AGL on all three points. Next, the cross polarity is not helping. The low dipole of Jerry is a mixed bag of polarity and pattern both H and V. Look forward to seeing the data.

Mel, K6KBE

Gents:

I have run into a problem here which, at least to me and a couple of other folks, we regard as "serious".

I am one of several people who are trying to make reliable contact for EMCOMMS purposes with a ham in Alaska, "Ed" Trump AL7N in Fairbanks, on 14115 CW.

His antenna is a 1.5 wavelength vee-beam pointed in "our" direction, and his power output is around 50 watts.

I have been having a very difficult time making reliable CW contact with him, despite running 600 watts output to my 55' vertical.

Within minutes of my being able to just barely hear him, and vice-versa, I make very reliable contact with Jerry KL7EDK on 14064 kHz, who is also in Fairbanks, via PACTOR, when I am running 50 watts, and Jerry is running around 30 watts output. Jerry's signal is WAAAAAAY above my noise level, whereas Ed's is at or below the noise level. Jerry's antenna is a compromise of some sort: a dipole I believe.

What I would like to request is to have someone here who knows how to do it to model Ed's antenna to see what its radiation pattern might be.

I hope to have all the necessary parameters later today.

I suspect his signal is bouncing over mine, and vice versa.

Any suggestions you folks might have would be very sincerely appreciated.

But he is 1700 miles from me, and there must be at least one polarity inversion via the ionosphere between us.

I suppose cross-polarity COULD be a problem, but since the other station, KL7EDK, is using a horizontal fan dipole with the center at 45 feet and the ends at 25 feet, I don't see how Ed's antenna polarity can be a factor.

But I've been wrong before....

Ken, the dipole at low level is a omni multipolarity radiator. Lots of vertical components.

Even at a distance of 1700 miles? I thought there was a polarity inversion, or even polarity rotation, at each transition of the ionosphere, and thus at HF polarity doesn't mean very much over a long distance.

Thank you, Mel. I appreciate that very much. As soon as I have all the necessary info, I'll pass it on to you.

I suspect Ed's antenna is simply much too low.

Jerry's antenna is a fan dipole with the center at 45' and the ends at 25'.

OK. Makes sense.

Still, I was always under the impression that polarity at HF over long distances did not make much difference since the polarity at the receiving end might be anything due to ionospheric rotation of the transmitted signal.

I would also suggest using VOACAP propogation prediction site to make sure when the best time and frequency is. If the path is no good the best antenna won't help.

Try a digital mode that works, in some cases, better than CW. We use Olivia in SATERN with good results.

Hi, Steve:

I have ITSHFBC which is part of the software suite designed by the same
fellow who did VOACAP, and I have input to that my antenna parameters,
and I update the SFI daily.

I have had pretty good luck with it over the past several years. It is usually at
least 80% accurate.

Secondly, I use PACTOR with KL7EDK and it has proven to be very reliable.

Somewhere n this post is the right answer.I believe between the owners manual and the technical knowledge base of the individuals on this forum it was not hard to figure out.10.7 MHz is the intermediate frequency of a simple FM radio.With up conversion and down conversion - I won't say HF radio - because that is no longer true.A old FM radio or a FM radio station would definitely put out enough RF to mess with your 30 meter antenna analysis...

Sigh....I am not surprised.

There is yet more that makes me think that a significant portion of his signal output is going straight into the ground.

In addition, the HIGH end is only up 25 feet, and the low ends are grounded (!).

I'll pass on to you what he sent to me privately.

The Alaskan station is said to be using a "V" antenna, that is not
the same thing as a dipole.
(and it is most likely not aimed at the sky)

> Still, I was always under the impression that polarity at HF over long

The ARRL handbook use to state: "after *several* bounces between the
ionosphere and earth the polarity will be altered" or words to that
effect. I did not know this circuit was defiantly using the ionosphere,
and I certainly did not imagine this to be a multiple hop connection.
I would get other members (of your local HAM club) to assist you by
pointing their beams at this station at the appropriate time and if they
can hear him, try to make contact. If no one can his antenna falls suspect.

There two kinds of antennas, one is to contact anyone, a 55' vertical
on 20 meters falls into that category, the other is to contact a
specific area, a beam, oriented dipole (and a "V" antenna) are just what
you need. All my opinions.

What he is using, or attempting to use, is a very low (25 feet) vee-beam, with
110 foot long legs, with the ends grounded. (!!!)

From my experience, and from Mel's antenna modeling (thanks, Mel), he has
a worm-warmer or ground-defroster. He can only run about 90 watts output
at most too.

> The ARRL handbook use to state: "after *several* bounces between the

Yes. I remember that.

> I did not know this circuit was defiantly using the ionosphere,
> and I certainly did not imagine this to be a multiple hop connection.

Well, he is a little less than 1700 miles from me. At that distance on 20
meters, I am certain ground wave would be gone. Therefore, ionospheric
propagation is indicated. BUT, undoubtedly, only ONE hop. Therefore, no
polarization change. Still, I very much doubt that ONLY cross-polarization on
20 meters would result in an apparent signal level difference of around 30
db...

> I would get other members (of your local HAM club) to assist you by
> pointing their beams at this station at the appropriate time and if they
> can hear him, try to make contact. If no one can his antenna falls suspect.

There are several other ops with beams who are further to the west from me
(at least 300 miles) who successfully contact him, although they all complain
that his signal is always weak or marginal

> There two kinds of antennas, one is to contact anyone, a 55' vertical
> on 20 meters falls into that category, the other is to contact a
> specific area, a beam, oriented dipole (and a "V" antenna) are just what

And good opinions too. Thanks.

He and I are discussing his options.

Due to his situation, multiple supports are not possible, as is a height greater
than about 33'.

I have suggested to him an OWL-fed inverted vee would work far better than what he is presently using...but, again, I have been wrong before, and will be wrong again.

From: Jay
Topic: 33581 Message: 33617

Thanks everyone for the comments. I'm always amazed at the number of responses, ideas and theories. I thought I would send one reply because I received so may responses. The radials are all insulated copper wire and they were stapled to the lawn and soon disappeared. I really have no way of gauging a beginning performance and always relied on the AH4 mounted at the base, it tunes almost instantly. I have worked the furthest distances from my home with 100 watts and of course good conditions just as years went on and the harsh New England winters I just wondered if they were still there or if made sense to try to add more however they would cross the ones that are there.

Thanks for all the help

Jay N1FDX

And you want to live in the middle of a desert...why? You'd be going from one of the wettest areas of the country to one of the driest. Quite a swing in environment.

If warm is what you are after, you can certainly do better than Vegas. Texas is a good choice. Conservative values in most places. But there are plenty of nice places in many southern states if it is warm that you are after. I like to visit Vegas, but living there, no thanks. Gets hotter than Hades and dry as a bone. Building a city in the middle of a desert just makes no sense to me. But to each his own. I know some people love it.

Personally, I like the weather of the mountains of Wyoming. But I am not averse to snow and cold weather either. People tell me I'm nuts for liking the cold weather. Again, to each his own.

I wish you luck on deciding where to live. But as a ham, definitely stay away from HOA's and the 'burbs. You need something a bit more rural. You don't have to be in the boonies, but somewhere that you can afford a couple of acres and is quiet, both in traffic and electrically.

73,

Scott AC8DE

Gents on the list:

If Eugene is anywhere near the coast, the Oregon coast is cloud-covered, thick overcast, and gloomy most of the year.

I can understand why Dave wants to move somewhere with better weather.

I agree with someone else who mentioned Wyoming. Very nice place. I lived there for a couple of years when I was just starting grade school. Still remember it with fondness.

The rain is my primary reason for moving... As I get older, the rain gets worse... :) It rains here for 8 months out of the year...

I like the desert... But have not lived there yet. I am a bit worried about water in the SW... Sounds like getting property out in the stix for antenna won't be an issue...

Hi Dave. I am helping my daughter move to eastern WA. Perhaps you should think about this area.
It seems like a desert, but irrigation from the Columbia keeps everything green.

Check out the real estate around Kennewick. You may see something you like.

Dave
Dave has a good point ...Spokane is certainly dry something on the order of 12" of moisture a year Only problem is 2/3 of that is snow :-(... You get all the convenience of a good sized city and you can get out in the country very quickly .. I lived there for 5 years (as N7EX) if the fishing were better year round I would consider retiring there

Reno, NV and Albuquerque, NM are also worth a look see

Dave
NR1DX (ex N7EX)

What about the Denver or Colorado Springs area? A moderate mix of mild seasons sprinkled with bouts of 3 day snow events that make you wonder why you've lived anywhere else. Want mountains? A drive west into the mountains will change your perspective. Want flat plains? Drive east.

A drawback is the landlocked first hop 20m propagation is still over land, grr. I still fight that when I'm out QRP portable. CA, TX, and NW are the easiest but try to go east like the upper New England states during our dismal solar cycle good luck.

We looked at several places and ended up in NW Arkansas. Great economy during a major recession, good weather but all four seasons, lots of lakes, rivers and streams not yet spoiled, and wonderful people, including a great ham radio community. Cost of living is not bad either. Anything I need is very accessible or else I can get delivered in a couple days to my door.And cheap flights to Las Vegas if that is where you to visit! Just my two pesos worth....73, WB0YEX

I wouldhave to agree withMyron, that is why (along with the fact the kids and grandkids live here) the wife and I retired here in Colorado. Though there are some communities that do have CC&R’s, there are many rural areas that do not.

I spent alot of time in NW Arkansas and agree it is a really good place to consider. Mostly out of the Tornado channel, mostly, green all year, fishing is great, people are really old country in the rural areas around Eureka Springs and Berryville. VERY little in HOAs. Good ham community. Good airport in Fayetteville. My 2cents worth.Mel, K6KBE

I'm with you Scott.
I did like Phonenix, Arizona in the winter.
If I could stand the long winters I would live in Wyoming in a heart beat.
I fell in love with Laramie.

For OP Middle Tennessee isn't bad and there many HOA's here especially
if you live outside of the city limits.
Here in Cookeville all you have to do is be about 2 or 3 miles out of
the city limits and your golden, so long as you don't buy in a sub-division.

A few acres in the middle of Missouri , your antenna tower limits are only by the depth of your pocket book. My pockets are not very deep so I put up a small 160M loop but have room for one 10 times that big and no permits are needed. I don’t like it dry.

Thank-you Van - For some reason the posting you replied with looks quite garbled in format on my computer but it looks to me like it is a series of 10 web-links to antenna related articles. I will start reading through them all when I get back from vacation but before I do, was that your intent, that these articles would answer the question about rules of thumb, or calculating the safe spacing between these 3 antennas I mentioned?

Thanks again

Kevin

hi kevin, yes, it looked like these sites could do a pretty good job
of giving you the data/rules of thumb that you were looking for.

I use a compass to show North and visually align the beam. The beam width is large enough to not worry if it is 5 to 10 degrees left or right. Now large VHF antennas are more critical.

True North, just factor in the magnetic variation. Use a
Aviation sectional chart to show the variation,
or just google the internet for the town/variation.
Then factor it into the true heading.

You use geographic north (true north) ... and when you measure that with a compass you have to use a local correction factor (local magnetic misleading) ....

I would use a (precise) topographical map and some landmarks

... some rotator controllers have a finetuning ... so then you only need to be precise to a few degrees

...

How big is the beamwidth of your planned antennas?!?

If it is for shortwave or vhf ... then don☐t worry about all that

Only if you wanna use it for sat work with azimuth and elevation ... and on very high frequencies with narrow beam antennas ... then you need to be very precise

Hello chuck

That really depends on what antennas are planned on the tower :-)

Say you wanna use the tower for antennas on the shf bands with a dish antenna (mounted on tower to have a clear view around horizon)

Or narrow beam antennas for moon bounce or sat work

Not all towers are for shortwave beams!!

Technically you should use true north. All of the beam heading tables
that you can print out bearings to a given country from your QTH and the
circular polar projection maps are all based on true north.

In practice most HF beams do not have a narrow enough beam width that a
a pointing error of 10 degrees will be noticeable.

Sigi, I contend to install a moon bounce antenna on a 50ft tower is a
hindrance rather than an advantage . Fifty feet is of little help
when transmitting 240,000 miles but the normal sway on the structure
might prove to be disruptive. Just thinking out loud ! Chuck Wq5B

From: Frank Kirschner
Topic: 33636 Message: 33646

I used the North Star. I sighted it at night, and found the spot on the horizon directly below it, and then aligned the beam with that spot during the day.

The beam width of my TH-11 is probably +/- 15 degrees, so precision isn't really required. It does seem to work properly, peaking signals when the rotor control indicates the correct direction.

I've done likewise. This method is good to 0.7 degrees or better if the
fact that Polaris is not exactly at true north is taken into account.
(Well, it is, like a broken clock, exactly north twice a day. Any star
north of the celestial equator is, come to think of it.) But I reckoned
that my method (eyeball, plumb bob, tape measures) was going to swamp
that error.

I did this when making a map of my yard. Comparison of the map with the
Google map satellite view of the proppity suggested that using Polaris
worked out well. Since the house has straight lines and these show up
well on the satellite (actually, I suspect, aerial) view, I suggest to
others that they look at that on Google (or rival) map services. Lat &
longitude lines appear on some of these views, and my impression is that
true north is straight up on these maps. Can anyone verify that?

Another way of finding true north is with a vertical stick and
a cloudless sky. Stick the stick in flat ground. At local noon,
its shadow points due north. The shadow is *shortest* at local noon.
To be more accurate, use a plumb line and know when local noon is in UTC
(i.e. know your longitude and time zone).

> The beam width of my TH-11 is probably +/- 15 degrees, so precision isn't
> really required. It does seem to work properly, peaking signals when the
> rotor control indicates the correct direction.

Some places in North America have a magnetic declination ("error") of
20 degrees, Maine and the Canadian Maritimes, for example. That may be
enough to matter. There's a world map at

https://en.wikipedia.org/wiki/File:World_Magnetic_Declination_2010.pdf

I don't think this map takes local factors like large deposits of
magnetic metals into account. But maps from government surveys will.

A ham in Maine could be over 3 db down by ignoring his large declination.
(Assuming 3db beamwidth of 30 degrees).

But, for our lifetimes at least, Polaris abides!

Maps work off true north
With most beam antennas having a beam width of 10 degrees +~- by the time your signal travels a few hundred kilometres it is a moot point to use either true or magnetic north
Only really becomes critical at higher frequencies and for moon bounce or satellite communication

Joe;
Been there, done that.....days we used to tune via the grid and load then cut. Modern rig, transmit shuts down at band edges and near as I can tell I am resonate lower than 1.8. How much lower I don't know and even with a dummy load, the transmitter would still shut down. Know it's got to be shorter, but ya can't add on, what you cut off.
Don't belong to any club (I'm kinda a loner, don't even have vhf equip.). Do have one friend that has one, but he is on the east coast vacationing, besides the climbing belt I borrow to use on my tower work has some duck tape on it. Has not given yet..... hi hi

With regards to which north to use can you not line it up (best copy) on a beacon or two. You would know the beacon's location.

Start Google Earth.

In the search box, type "North Pole".

Click on "Tools" and then "Ruler".
Using the ruler function, draw a line from the North Pole to your tower. You will have to play around with this to figure it out. As a hint, draw a line, then zoom out. Then move the cursor to the end of the line,? (it will turn into a hand), click and drag, then zoom out again. Keep doing this until you have extended the line from the North Pole to your tower. If you have a wheel on your mouse, its easier.

The yellow line will point to true north, the only TRUE heading. Using the yellow line as a reference and intersect on the map, find a know reference (a neighbor's house or a big tree) and point your antenna at it.

Simple! I've done this on the tower with my smart phone.

?

When erecting a beam-type antenna, do you use true north or magnetic north?

33661. Cushcraft 6 Meter Beam seems a bit different from today's A50-3S

Yahoo group: ham-antennas (2014)
Date: 2014-08-17 17:22:33 UTC
From: myfamilydotcom@...
Topic: 33661 Message: 33661

I bought a well-used Cushcraft 6 meter 3-element beam from a fellow at an out-of-area hamfest recently. I was fairly sure that it was a Cushcraft A50-3S and the hardware looks very similar except that:
Mine has a one-piece director (102x5/8") and one-piece reflector (115" x 3/4") whereas the A50-3S has these elements in 3 telescoping sections The boom length is the same as the A50-3S handbook shows but the spacing is much different; it appears that the previous owner mounted the driven element equidistant from the director and reflector, whereas the A50-3S handbook places the driven element much closer to the director and further from the reflector. The gamma match appears to be very similar in overall length (what is called "SET") but the length of the exposed tube end "X" is about 2.5" as opposed to the A50-3S manual range listed at around 4.75" If I build this as a true A50-3S I'll probably have to re-tune the gamma match since the new director/reflactor spacing probably has a big impact on the driven element impedance, but the switch to one-piece elements also screws up the weight distribution and the A50-3S boom-to-mast clamp point is definitely not the centre of gravity.

Help: I'd like to see a copy of this beam's original equipment manual, which is probably a pre-cursor to today's A50-3S. Can anyone send me that (myfamilydotcom@hotmail.com) or offer more insight to th e 'slightly diffreent product? Only the current A50-3S manual is shown at Cushcraft's website.

Thanks

Kevin

I run a Windom, off center fed dipole…180 feet total. I live in Reno Nevada, where we DO get snow and ice, (But not like back East) but at my location, 1500 feet higher than Reno, have fierce winds all the time (many times a year, over 100MPH!) I made my Windom using 12 gauge flex wire…it is supported, along it's deployment, by a 10'x2"x2" Redwood, heartwood, post, every 10 feet. (The posts are lagged into my 'good neighbor' redwood fence). I lose a post or two a year , due to the wind action whipping my dipole wire, but have never (Tapping my head, you know. knocking on wood!) had any issues with my wire. I can (but not often, feed the wire with a California kilowatt (sic), which *does* melt any ice build-up, if any, and keeps the birds off their 'roost'.

My wire completely encircles 3 sides of my property, which has created some pretty funny (after the fact) happenings. The property on the West side of my house, is handy for that neighbor's back yard patio. The house was rented for a period of time and a new tenant, at that time, got all settled in and had a housewarming party. I came home from work and found an off the wall high SWR when I tried to get on the radio! Figuring something catastrophic had happened to my antenna, I went out to investigate, and found the entire length of the wire between my property and theirs, decorated with hanging Japanese lanterns, complete with electrical wires. Well, no one was home, at that house, so I got my ladder out and cut their lanterns down and just let them drop onto their side of the fence. About 2 hours later, the new neighbor was at my door. When I answered the door, the neighbor started screaming at me about destroying his property. When he finally took a breath, I explained to him that the wire was not his to do any with, in fact it was an antenna for ham radio. He then told me it was on 'his' fence so he could do anything he wished. At that time, I told him that was not true and if he touched my antenna again, he would be bucking Federal laws and could be jailed for doing so. I also told him the fence was built by me, a number of years before any other dwellings were erected in my neighborhood, so the fence was NOT his. He got belligerent again, but…lucky for me, a good friend, who is (was) a Washoe County Deputy Sheriff had stopped by to see a new gun I had purchased, and as he was on his way home after a shift, he still had his uniform on. He came to the door, introduced himself, and basically informed my irate neighbor, what I had said was true. And under no circumstances, do anything to the wire, and if it were damage in any way, at any time, he was a witness to the threats of damage and he would be arrested, on the spot, on Federal, felony charges. That renter moved out a month later as the house was sold to a now, great neighbor!

Well, There is more to the story, but as I have already hi-jacked this interesting thread, I will leave it for another time.

OK, back to wire. Just use a good grade of flex wire, with an appropriate gauge for the perceived amount of load, and ice and snow will not be an issue.

I had considered a loop at one time, but no way to get the 4th 'leg' around the front of my property, ie: no way to support a 100 foot run of wire, not to mention the protests from my wife.

Most of my radio work is on 17, 40, and 75/80. The wire is great for 40 and lower here (In actuality, it is pretty good for everything from 6 down)....but I do have a nice Hygain tri-band'er we are going roof mount on a well guyed Glen Martin, (House at its peak is 68 foot above ground elevation) and I will be swinging a Hygain 17m mono-band'er as well...hopefully, with judicious care and awareness of 'parking the beams' they will survive the winds here.....

Nascar this is definitely a Cushcraft - It is exactly the same as the Cushcraft product except for the differences I mentioned. The manufacturing details are exactly like the cushcraft yagis which I am familiar with. Based on further research I think it may have been prevously sold as a Cushcraft A50-3 (without the S designation, which singnifies older and not stainless steel hardware I believe).

If someone can steer me towards an old manual of this I'd be appreciative.

I prefer Texas myself. No zoning most parts, other than some incorporated cities, etc.
Beware HOA's and CC&Rs though.
They tend to get ridiculous.
However, it is hot in summer, winters mostly mild.
Dry in parts, and humid in others.
I am in a mostly dry area.
I moved here over 8 years ago, and am able to put up any antennas I want.
Can't afford a tower, was hoping to salvage a TV antenna tower or two, but that never happened.
Plus I am able to keep the animals I always wanted.
taxes fairly low, and plenty of places can be found if you take the time to search and search.
No income tax, and no state tax on lottery/gambling winnings.
of course, are always some drawbacks no matter where.
In Nevada, I would suggest Pahrump over Las Vegas any day.
But it is costlier there, and you need permits for many things.
here, the only permit needed was for the septic system that was put in...

Just my 2 dollars worth...
YMMV

33674. OCF question

Yahoo group: ham-antennas (2014)
Date: 2014-08-19 14:08:56 UTC
From: steve.lenaghan@...
Topic: 33674 Message: 33674

I have a 100' square yard with tall pines and I am running a 135' OCF diagonally. I am thinking of adding a 90' folded dipole to allow my radio to run MARS ALE without a tuner. If I run the new antenna along the side of my lot will the antennas interact? Besides CFARS (Canadian MARS) we exercise with the military on their frequencies none of which are harmonically related.

From: Artek Manuals
Topic: 33674 Message: 33675

There will be interaction but likely not a lot since I don't think
either antenna is a near multiple of a 1/4 wave and the antennas are not
parallel to each other. The interaction could be minimized by running
the antennas at right angles. i.e run the 90' antenna across the other
diagonal of the lot with even only 1 foot of separation at the crossing
point is not a concern.

Hi,
Has anyone used a 30 Meter GAP mono band vertical dipole? If so, what are your thoughts on it. How did it compare to a monopole vertical with ground radials?

Any thoughts at all would be helpful in my decision making process. Remember, the GAP MONO's are vertical dipoles, not vertical monopoles... Thoughts?

From: Joe
Topic: 33677 Message: 33677
Attachments: 1 described; binary payloads are missing from this source WARC

As someone with old Equipment, Drake TR-4, Kenwood TS-430S none have the ability to "Talk" to any other equipment. Computers, Tuners etc.

During Field Day they had a Icom 718 and a matching tuner from some company. It was I have to admit pretty cool. If it was the first time on a band or freq you pushed a button on the rig and it transmitted a low power signal and the tuner and the rig automatically tuned for min SWR, pretty neat. Then from then on later on if you changed bands and ended up near the same freq, as soon as you set the radio there the runer already knew the settings for best match and even before transmitting set itself to what was a good match last time. Cool.

Now I know these old rigs can not do that.

But can any of these tuners do an auto tune without talking to the rig?

Like if I wanted to tune up I'd set it at a low level 5 to 10 watts and hit a button on the tuner. and it auto tunes.

are there any tuners like that?

I have all sorts of tuners here from Johnson KW to home brew roller ones.

But Man-O-Man that auto tuning sure is nice. So can they operate with old rigs like mine with no computer talking at all?

Joe asked:

"But can any of these tuners do an auto tune without talking to the rig?"

I am fairly sure the SGC autotuners (and maybe others) can do pretty much just that. You transmit on a new frequency, they see you transmitting and take a second or two to auto-tune, and done. You transmit again on a frequency in its memory, they recall the settings, and done ... within milliseconds. Well maybe not that fast, but almost instantaneous, much less than a second.

I *think* they don't even need you to tune-up on low power. And I'm pretty sure they do it just fine even with SSB, which can be tricky for some auto-tuners.

Wish I had the spare cash sitting around for one.

Regards,
Andy

I have an Elecraft KAT500 that will work with any radio. They say it will tune with just 10 watts but prefers 20+ watts. It will handle up to 500 watts and tune up to 10 - 1 swr on most bands. Check the Elecraft web site for more info. NFI here but I do have the complete Elecraft line up. Happy hunting.

I use an LDG At-100 ProII and a MFJ-993B, both of which need no input from the rig. Just put in about 10 watts, the thing rattles for a while (the LDG often for a LONG while), and the lights flash for a match. If you have tuned near there on that antenna recently, it just makes a quiet "click" and is there.
LDG is a good price, and you will need the AT-200 (200 watts) or the MFJ 993B (350 watts) for a TR4! I had one, and it is a hoss!

Hi,
I have an autotuner for the Yaesu FT-897 from LDG. In the manual it states you can just send a low power AM signal then hit the tune button and it will tune up any type of radio. For tuning the Yaesu, I connect the control cable as well as a coax jumper.

Hello roller coaster man ... yes ... modern autotuners can do that

My yaesu fc1000 works with any rig

Contacts needed is ptt, agc and 12v

With yaesu rigs the tuner talks with the rig (memory settings) ... wit all other rigs the memory function does not work

But after a qsy just a short tuning time is needed even without memory

...

My friend gas a cg3000 ... (almost similar to the sgc tuners)

That tuner does only need 12 v and nothing else

And those 12v power can be brought to the tuner via the coax (dc injector, phantom power, ...) ... so installing such a tuner at the antenna is really simple

Have you looked into Moxon or Hex Beams, you can build them mono or multi band , some do not have to be not far off the ground to work well , also Delta Loops are supposed to be quiet and far reaching , or an H " shaped Dipole it has a driven element and a reflector . Just some ideas to share , AJ W5HEH

The auto-tuner on myTS940 does just that. Pick your freq, push the tune button and it tunes for lowest VSWR.No talking no nothing, just hit the "tune" and away we go

33690. Assembling an old AVQ-12 groundplane

Yahoo group: ham-antennas (2014)
Date: 2014-08-20 17:02:02 UTC
From: michael.theiss@...
Topic: 33690 Message: 33690

Is there anybody in this Group who still has a manual (assembling instruction) for, or who still uses the first edition of the AVQ-12 from the late 60th ?
I need assembling details (length of the different pipes).
Note: The manual that is available on the internett is for the latest edition and does NOT give the necessary answers.
Even HyGain sent me an e-mail and told me that they do not have the necessary details any longer.
For stability reasons (wind resistance), HyGain changed the lay-out many years ago.
I know how it could be done w/o manual by "trying and testing" but this would be "hard work", because the GP is mounted on a 6 m high pipe.
Best regards
Mick, LI5SAA

Hi Chuck.
You are right, of course. I dont have an analyser (would like to have - but pretty expensive), but I can solve the problem by trial and error finding resonance, starting at 10 m, then 15, etc.
However, this could be a heck of a job.
Ronald has a manual of the old type AVQ-12, which would make things nicer and easier. I am at present e-mailing with him.
Hope to meet you on the bands some day. Here 90% CW.

Go and buy a sark100 or mini60

Very cheap antenna analyzer

Can be used together with pc (so you can see a whole sweep over complete shortwave range or just over band/s of interest)

Sark100 is a bit cheaper and does not have Bluetooth module (can be added for 5-10 bucks)

Mini60 has built in lithium battery and charger ...and is a bit smaller

And has Bluetooth module (you can do a sweep without cable to pc)

There is also an android soft available so you can see a sweep on a smart-phone

... I bought a sark100 and added the bt module by myself ...

If you are not so very well in modding/homebrewing ... then go for the mini60

33695. AW: [ham-antennas] Assembling an old AVQ-12 groundplane

Yahoo group: ham-antennas (2014)
Date: 2014-08-21 08:34:29 UTC
From: Michael Theiss
Topic: 33690 Message: 33695

Guten Morgen Sigi :-)
Thanks for you feedback. Very interesting, and I have spent some time googling and thinking.
None of the two can be bought from our Norwegian dealers - and I have had some problems with deliveries from e-bay or amazon thru the years.
See also the youtube video https://www.youtube.com/watch?v=c58E38VET_g
And: Around 200 Dollars (incl taxes) is a lot of money.
After years of experiments with antennas I have ended up with a 2 x 18 m doublet for all bands 80 to 6 m,
and a designated vertical with 7 elevated radials for the 60 m band (see photo at qrz.com for LA5SAA).
My xyl and the close-by neighbours are just accepting these things as they are. More is not possible here :-(.
During /p qrp operations I normally use end-fed antennas with a tuner, or designated inverted v dipoles from a telescopic mast.
I am more than 70 years old, and dont think I will build many more antennas, so the analyser is not really necessary any more, but would be "nice to have".
The old AVQ-12 has been hanging disassembled in cellars and later in my car port since about 1970, and I just want to test if it gives better results on dx than my doublet. If so, I would take the 60 m vertical down during summers when qrn is high on 60, and replace it with the AVQ-12 in june and july, when our nights are very short.
To buy an analyser just for assembling the AVQ-12 would be .... well ;-).
It's a pity that we are getting old and have to walk more slowly ;-).
Herzliche Grüsse
Mick LI5SAA ex DJ8EP

There are several brands that will do that when all you have to do is key 10 or so watts and push one button. Most will tune when you just start talking but using that feature can cause problems when

QRO. I use MFJ-998's have great performance even on 160M which some brands. The MFJ-998 will also shut off your amp if you run the cable through it with the provided RCA plugs.

There are other sources for swept frequency antenna analyzers. I recently purchased a kit from Fox Delta...Ham :: Amateur Radio Projects and kits by Fox Delta http://www.foxdelta.com/products/

http://www.foxdelta.com/products/

Ham :: Amateur Radio Projects and kits by Fox Delta http://www.foxdelta.com/products/ amateur radio projects and kits by fox delta

View on www.foxdelta.com http://www.foxdelta.com/products/
Preview by Yahoo

They can be purchased as a kit, partial kit, or assembled. Took a while to reach me as it was shipped from India... be patient.

LCD PIC18F2550/2553 35MHZ USB POWERED ANTENNA ANALYZER:AAZ-0912A: By Tony/I2TZK, Frank/k7sfn, Dinesh/VU2FD http://www.foxdelta.com/products/aaz-0912.htm

http://www.foxdelta.com/products/aaz-0912.htm

LCD PIC18F2550/2553 35MHZ USB POWERED ... http://www.foxdelta.com/products/aaz-0912.htm Forward & reflected RF Power Measurment with PIC16F88 microcontrllers by fox delta

View on www.foxdelta.com http://www.foxdelta.com/products/aaz-0912.htm
Preview by Yahoo

Partial kit, with shipping, was about 65$US. I purchased the partial kit because my skills at mounting surface mounted parts is not great.

The device will be powered by the USB from my laptop, which also collects the data and graphs it. Software is freely available at the web site.

Topic: 33690 Message: 33699

Over the past week or two, I have been dealing with what I, at least, have regarded as an important issue with an antenna system which is primarily being used for EMCOMM use in Alaska.

A station, AL7N, who has pretty much dedicated his life and station to providing reliable communications into and out of Alaska for emergency purposes, but who is very limited on both resources and available "territory" on which to install antennas, had been trying to use, as his primary antenna to communicate with the lower-48, his own design of a much too low vee-beam, made out of wire, and fed with home-made open-wire-line, and with the far ends grounded.

His signal here in the lower-48 has always been very marginal and difficult for any of us in the NorthWest and California to reliably use.

After considerable discussion with him, I asked two of our regular members here, (who shall both remain nameless in order to keep them from being inundated with similar requests), to both examine his present antenna with antenna pattern plotting programs and to suggest an alternative, better performing, antenna.

A plot of his present antenna with EZNEC proved that it was (in the words of the one who did the plot) "UGLY", with a very significant null in the vertical radiation pattern, and VERY low "gain". He termed it a "worm warmer or ground defroster".

After much discussion with AL7N, and after downloading and installing both EZNEC and MMANA-GAL, and plotting some results, I suggested to AL7N that he install an inverted-vee, fed with his OWL.

The results, although not "spectacular", are VERY much improved. Whereas on his previous antenna, his signal was always just above the local noise level at any of several receiving stations here in the NorthWest and California, his signal level is now 579 in most places.

We are all very pleased, and I wish to publically thank both of the members of our forum who helped. You know who you are, and, again, I thank you heartily.

vy 73,

Ken W7EKB

Nabend Mick

I bought the sark for

Around 90 dollars (70 euros) ... free shipping!

(and nothing else!!!)

http://www.aliexpress.com/item/New-ANT-SWR-Antenna-Analyzer-Meter-For-SARK100-Ham-Radio-Hobbists/1986217675.html

the mini60 does cost just a bit more

around 128 dollars (97 euros) ... also with free shipping

http://www.aliexpress.com/item/2014-Brand-New-1Pcs-Mini-HF-ANT-SWR-Antenna-Analyzer-SARK100-For-Ham-Radio-Hobbists-1/1989698377.html

both can be used standalone in the field (lcd display) ...

or connected to pc/laptop ... or to an android smartphone

sark100 via usb (but adding bt module does only cost around 5-10 dollars)

and mini60 via usb and Bluetooth (ready to use)

.....

Where did you find 200 dollars?!?

Dg9bfc

Sigi

Ps ... I know no spamming in this group ... but sure these cheap analyzers are also interesting for others... if you only need shortwave ... that is cheapest solution

Neither had I. He figured that since he didn't have any large 600 ohm resistors, and that since his ground conductivity was very low, that grounding them would be better than not. **I** thought he was wrong, but had to go through some long discussions to prove it.

> At least it doesn't seem right to me.

Well, it sure as heck didn't seem right to me either...in addition, it was at a height of 25 feet. IMHO, vee-beams don't really work at a height less than one wavelength.

33704. Multiband moxon design

Yahoo group: ham-antennas (2014)
Date: 2014-08-22 08:04:17 UTC
From: Billy McFarland
Topic: 33704 Message: 33704

Hello all,

I was thinking of building a portable moxon for one of my friends. I have found this design on line.

http://www.moxonantennaproject.com/TA3GO/TC3EC.htm

I was just wondering if anyone knows how thieves fed. It looks like a single price of coax running the full length feeding each driven element and then a choke balun at the end. Any thoughts?

33707. How Do You Search Yahoo Groups

Yahoo group: ham-antennas (2014)
Date: 2014-08-22 20:59:29 UTC
From: dbutler1949@...
Topic: 33707 Message: 33707

I am trying to search this forum and another by putting double quotes around the search topic and keep getting the following error message: "Sorry, an error occurred while loading the content."

So how do I search for a specific topic. Dennis, N5OTH

PS: single quote (or whatever it is called) doesn't work either....

33708. Re: [ham-antennas] How Do You Search Yahoo Groups

Yahoo group: ham-antennas (2014)

From: Andy
Topic: 33707 Message: 33708

I usually don't use quotes. If you need them, try them, but be ready if they don't work.

Yahoo's search function is horrible. Yahoo has had problems with it since ... forever. Your error message might simply be this week's problem. Yahoo's programmers seem to be particularly adept at adding new bugs while removing a few of the old ones.

Andy

From: Andy
Topic: 33707 Message: 33710

I just tried a search with and without quotes.

The one without quotes apparently finds any messages with the search term words, together or not.

The search with the quotes worked correctly! No error message.

So I'm guessing either you caught Yahoo when they had a bug going on, or maybe there was an issue with your web browser? Try again, or try another browser or another computer.

Sometimes it also helps to get to Yahoo's "Advanced search" page. To do that, you need to do one successful search (of anything), then click on the "Advanced search" button. It gives you more control over your search. Although, it looks like Yahoo has dumbed down that one as well. :-(

Andy

This likely won't work with Yahoo Groups but it does work well with other message boards most of which have lousy 1990's era search engines that have been outdated for well over a decade. If you are using Firefox or a derivative you can enter this in the address bar.It's real simple .... first your search term, I'll use 'collinear antennas' then the site you want google to search specifically by using the following .... site:name of website

So you end up with this

collinear antennas site:groups.yahoo.com

Just copy and paste that into your address bar or the Google search page and you'll get a bunch of hits. The problem with groups however is this search all Yahoo Groups not just the this one

Google's search technology just can't be beat ... so far.

I also recommend everyone reads this page because there are a lot of good tips on making Google search more productive.

From: Geoff NW7GM
Topic: 33704 Message: 33717

I am considering a 6m Moxon and will be putting a 1:1 toroidal choke at the feed point. I don't like the air-wound coax choke idea that most use (if any) when they build these antennas.

Maybe make your balun with a FT140-61 toroid with 8 turns of RG316 and place it into a box, similar to how Steve (G3TXQ) makes his Cobweb balun box and attach your 3 driven elements to that (maintaining proper element separation of course).

Andy - YL2QN

33724. 1:1 ununs/ Chokes (From Moxon Discussion)

Yahoo group: ham-antennas (2014)
Date: 2014-08-26 13:50:46 UTC
From: Scott Myers
Topic: 33704 Message: 33724

Ah. 1:1 ununs on toroids. I've made a few. I too prefer the M17 family of coax for this purpose. Nothing like teflon and silver plated coax. Pricey, but never fails. You can make it once and forget about it. The basic design of that particular toroidal choke type used by G3TXQ was published by W1JR (J Reisert) in 1978 and later published more widely W2FMI (J Sevik). G3TXQ does a great job of showing choking values on various cores and wrap numbers on his website. Several companies sell chokes/ununs of this design wound on 2.4" type 31 or 43 cores.

I've landed on using RG303 myself for practical reasons. It will handle a full 1.5 gallon, even down on 80 & 160 and not burn out. I'm told the design has been tested to 5 KW, but I can't confirm that. I will admit I've not tested RG316 at power, but it is so small, I'm a bit nervous about trying it. I can also solder/crimp N's & PL259's directly to RG303, but I don't know how one would with RG316. (Maybe there is a connector made to do this. I don't know.) The nice thing about putting connectors directly on the RG303 is that then I don't have to put the unun in a box at all if I don't want to. Just wrap it with some silicone tape and all is well. Makes for a more compact arrangement. But you can't go more than about a .8" radius on RG303. And of course, any of the M17 coax is quite stiff for its diameter. And of course, it's pricey. There's always downsides. Costs about $20 per unun, sans connectors; $7 toroid, $3 per foot on coax. I use about 3 feet on the core but start with 4+ feet due to the stiffness and not knowing exactly how long I want it's "tails".

Of course, you'd never get RG303 on the 1.4" core so if you want one that small, you'll be using the RG316 for sure. That stuff could certainly take a 0.5" radius.

Of course, bifilar wound is always a cheaper option but that definitely has to be in a box.

73,

Scott AC8DE

33725. Re: Cushcraft 6 Meter Beam seems a bit different from today's A50-3S

Yahoo group: ham-antennas (2014)
Date: 2014-08-26 16:04:42 UTC
From: myfamilydotcom@...
Topic: 33661 Message: 33725

UPDATE: I never heard from anybody who could locate the older manual for this antenna (called the A50-3, not A50-3S I believe now), however I have noticed that the big brother antenna called the A50-5S (with 5 elements) also has equidistant reflector, driven element and 1st director spacing. I assembled this 3 element model as if it were the first part of the 5 element model and tested that.

While experimenting with various lengths of driven element and gamma match settings, I have documented the settings now for a 1:1.0 match at 51.6 MHz and at that point I see a 2.6 MHz bandwidth (for VSWR of 2:1 I mean).

All the tuning and experimenting was fun, and somewhat similar to what the A50-5S manual woulld have suggested.

An interesting point was that the resonant bandwidth on the ground (i.e. reflector on ground, antenna pointing upward and resting on a 10' mast) was about 300 KHz higher than when in air horizontally with same settings.

Also, the Cushcraft element length settings are vastly different when switching between horizontal and vertical configurations (maybe because of capacitive coupling to the mast?) - I hadn't realized that.

Kevin

Hi - I'm using an Alpha Delta DX-Ultra fan dipole for SWL'ing. It's cut to favor the SW bands.
I now want to try and earn my Tech/General ham tickets at this late stage in the game, I'm 58 years old, and am now listening, and learning, to the ham bands only.
If anyone is familiar with the Alpha Delta, can I trim the wires on this antenna to receive the ham bands better or will there be not much of a difference 'receiving wise' ?
The apex of my antenna right now is only about 17' but I'm going to get it up to 35'.

Depends on what bands the dipole is designed for now. And what ham bands you want to listen to. For the ham bands that are close to the dipole frequencies it won't make much of a difference.

33729. Assembling an old AVQ-12 groundplane - testing finished

Yahoo group: ham-antennas (2014)
Date: 2014-08-27 08:38:17 UTC
From: Michael Theiss
Topic: 33690 Message: 33729

Thanks to all of you who helped me to get my old AVQ-12 S assembled and tuned. With all the info, I needed about 1 1/2 hour to reach an SWR of abt 1.3 : 1 on all bands at cw - qrgs. I tested the performance of the antenna in several qso's on 20 m with USA East Coast and Middle West - by quick-switching between the AVQ and my 2x18 m doublet that you can see on qrz.com for LA5SAA.

The result of the tests is about what I expected, but wanted to confirm.
On my transmitting, the signal with the AVQ was always weaker (3 - 6 dB) than the doublet.
On my receiving, the AVQ gave about 6 dB more "white noise" than my doublet.

So, at present, the AVQ-12 does not give any benefit to me, and I have already removed it and stored it again in my car-port. At least my xyl is happy now.

From: Michael Theiss
Topic: 33690 Message: 33731

Hi AJ.
Yes, we all are in love with XARA :-).
The mast in the center of the doublet is 35 feet high, the two ends are slooping down to about 15 feet.
The antenna works great an all bands from 10 to 30 m. Going to 40 m, things are not so good in DX, and DX on 80 m is difficult in normal condx. This is because the antenna is too low for DX on 80 (and 40).
However, such an antenna is a great compromise, and is the best I can put up here.
Yagi's require nowadays here a special permission from the authorities, and a "Yes" from all direct neighbours.
Have a nice day.

I am currently using a G5RV 80 thru 6 mtrs. I live in a mobile home community and would like to try a vertical HF and there are so many choices and my wallet isn't very big on cost. I would appreciate any ideas. I have some room behind our home on the pad and also behind our shed. I thought about trying to get one of the old TV antenna's that you put up beside the house, but seems they are hard to find these days. Thanks in advance for all.

Gerry,

A friend gave me a 4-band trap Hy-Gain14 AVQ (about 18' tall) that had been sitting unused behind his shed for decades. Another ham had given it to him. I used steel wool to clean it, replaced hardware, then borrowed an antenna analyzer to adjust it. A construction company was getting rid of unused galvanized mesh, so I bought 3 rolls of 100' x 3' (or maybe 3.5'?) from them at a great price, and used a blow torch to connect wire since you can't solder it. I unrolled them at 60 degrees from each other, crossing at their centers, for the ground plane.
The vertical is noticably noisier than my dipole, but I don't need a tuner and get out well. My second QSO from Pennsylvania was to Cambodia! I was running 100 W. I continue to make many State side and dx contacts so am happy with it. It isn't a tower mounted Yagi, but I'd recommend giving it a try if you have a few hundred bucks to spare. If less money than that is available, you might suspend a wire from a rope in a tree to wire radials on the ground. Just be sure to leave some distance from the trunk.

GL es 73,
Mike ab3ap

Gerry.
You may try to get hold in used windsurfing masts. At least here in Norway, people dont do windsurfing any more, but kiting is the big thing today.
It depends, of course, if you live near places where windsurfing was done. I announced my wish in the local newspaper, and got many masts for about 10 Dollars each.
You can put the masts into each other, and then you have a VERY STRONG construction running a thick wire along the mast combination as the radiator of a vertical.

Gerry,

Two things to think about:

Ground plane

Attenuation from Aluminum siding in close proximity when ground mounting

Verticals require a ground plane. Forget about "no radial" verticals. You can't beat old man physics. I'd search hard from some TV tower and do a couple multiband tuned radials with cage dipole separators. Now if your trailer has a metal roof, that would be an awesome ground plane.

Mounting on the ground around all those aluminum skinned boxes doesn't sound like a recipe for good signal propagation. I have no experience with such a situation though, but I'm sure someone here has. Maybe it isn't as bad as I would think it is.

Even if you don't pass the General test, you will have some privliges on HF as a Tech. However, they will be in the CW portion of the 80, 40 and 15m bands. On 10m you would have some CW access from 28-28.3MHz and phone from 28.3-28.5MHz. Both of those segments would be limited to 200w PEP. I believe that the 200w limit would apply to the rest of the HF segments as well.. but, trust me, 200w would be plenty to work the world.

Good luck on your test.

Ha!

I've worked 35 countries on 40 meters with an ex-military transmitter whose
INPUT power is 15 watts at maximum. Crystal controlled and feeding an
end-fed wire, too.

The AN/GRC-109. Look it up on Google.

I used its receiver too.

Thanks Geoff - That's good to know but I have a question -
Even though I'm not licensed yet, can I still purchase a transceiver on-line or at a store ?
Will they ask me for my callsign, which I obviously don't have, so will that be a problem ?
I'm just listening now on an ICOM IC-R75. I know it's illegal to transmit without being licensed, but I wanted to know if a tranceivers' reception would be a little better than the rig I have now. I plan to spend in the $2500.00/$3000.00 range for my first rig.
Thanks,
  Mark

INPUT power is 15 watts at maximum. Crystal controlled and feeding an
end-fed wire, too.

The AN/GRC-109. Look it up on Google.

I used its receiver too.

Mark,
No dealer should turn you away from the almighty dollar. I appreciate your intentions. When I was a "lowly technician" I purchased a Yaesu FT-100D, no cheap rig. My wife and I decided that if nothing else, an investment in my future hobby growth was positive. I'm now an Extra licensee, teach and run a VE team. Congrats and good luck. Also, testing once and not passing is not a sin, just go back again. Try to be as prepared as you can when you go test, don't take it lightly. It's a great life!

If you wanna spend such a high amount of bucks ... then buy a used rig and for the rest ... invest in some antennas and other things needed (tuner, poles, swr metre, antenna analyzer etc etc)

33749. Re: AW: [ham-antennas] Re:

Yahoo group: ham-antennas (2014)
Date: 2014-08-27 19:05:47 UTC
From: Robert Cavanaugh
Topic: 33726 Message: 33749

Mark,
Getting multiple classes on the same test day is not weird and also completely do-able. I had a Novice license in the 1970's that I let lapse when I was in college and never got back to it. Recently I got back into amateur radio and passed my Technician, General, and Amateur Extra tests at the same examination. If you try and don't make it, no harm, no foul, try again. If you do make it, you save multiple testing fees :-)

HRO was happy to sell me my Yaesu FT-897 before I received my cert letter. The hams running the store made it VERY clear that I could only listen in until I was licensed, but it is not regulated like a gun store if that is what you are thinking.

GO for it!

73,
Bob Cavanaugh, AG6YK

Not passing certainly isn't a sin... Took me two times to pass my General, then I took a class to get my Extra ticket. Glad there isn't any more testing for me. ;)

Mark,
Getting multiple classes on the same test day is not weird and also completely do-able. I had a Novice license in the 1970's that I let lapse when I was in college and never got back to it. Recently I got back into amateur radio and passed my Technician, General, and Amateur Extra tests at the same examination. If you try and don't make it, no harm, no foul, try again. If you do make it, you save multiple testing fees :-)

HRO was happy to sell me my Yaesu FT-897 before I received my cert letter. The hams running the store made it VERY clear that I could only listen in until I was licensed, but it is not regulated like a gun store if that is what you are thinking.

GO for it!

Ground mounting is difficult with all the metal around you.
Do you have any tall trees near you? Can you afford a 43 foot telescoping pole?

I use a 88 ft doublet , mounted as an inverted "L" with the center feed point at the top of a 40 foot bamboo pole and the lower 14 foot horizontal , above head height. The top 44 ft slopes down to
another pole about 20 foot tall. It is fed with 300 ohm parallel line, 450 line works well also, at the apex. The feedline ends in a 1 to 1 balun and then short coax into the station to the LDG pro1 tuner.
I work 80 to 10 with good results.
It would help to know your situation with any antenna supports.

The tests are pretty basic. If you have an iPhone download the three tests and do practice exams for a couple weeks and you will pass them all. I studied on the Internet and used those apps for practice exams and three weeks later had all three licenses. Just beware that some of the old timers don't like how much they have dumbed down the testing process so be ready for that.

Once you get on the bands, keep listening to QSOs and when you think you understand the exchange well enough then go for it. Remember that there is a DX Code of Conduct so read through that. Try your best to abide by it and you will do better than half the hams who are on the bands. General courtesy can be lacking and some old timers like to blame newer hams but if you listen long enough the offenders are in both groups.

In terms of your fan dipole, I would find a local ham in your area that has an antenna analyzer. Simple antenna theory should give you an understanding whether you will have to trim or augment the different dipoles.

Good luck and have fun!!!

Scott,

In all fairness, some of the verticals that claim "no radials" are in fact OK: they are vertical dipoles, center fed, (or some other type not requiring a ground), which is just fine.

But in general, yeah, I'm with you. There are some really amazing antennas that exist only in advertisements.

I've got a nice barn with a metal roof, but, dang it all, it runs just across a narrow lane from the power line. It *might* be far enough away to put up a 20m 1/4 wave, but it would be testing fate.

An additional note on vertical antennas and specifically the OCF vertical dipole. Look up my write up in the files. I have found that the 80 M OCF vertical dipole is quieter than the full size 1/4 wave vertical 500 feet away in the same 40 acre parcel. No power lines, everything on the property from the house at one corner of the property is underground. Not sure why it is quieter as the 80 M is mostly vertically polarized like the 1/4 wave, but a S unit or more many times switching back and forth. The beauty of this antenna is that with the tuning coil I can tune it to 7 MHz where it is now mostly horizontally polarized and is just as quiet as my SteppIR dipole. Just some thoughts.

AJ, I think we pronounce the X like you in the USA, that would be something like "Ksahrah" :-). By the way, all bands are almost dead here this early morning (3 am local time). We have a high K-index which is very bad for condx from/to Norway.So Xara and me get some more sleep. 73 es GN.

I do not think there is any translation for Xara, AJ. A popular designing software has the name Xara. However, I gave her this name because I have romantic memories to the town "La Xara" at the Costa Blanca in Spain, where I was for some weeks when I was 19 years old.
One never forgets the "first time".
My XYL does not know anything about that, and she really does not need not know ;-)

My roof is shingled. the pine tree that I have my G5 up in is about 30 feet tall. and the leads are I think 52 feet across which we have up in adjacent pine trees. I've been looking for an old TV antenna tower and could possibly set that in concrete in the middle of the back yard or on the remainder of the the concrete pad the house sits on or behind the shed which is separate from the house but next to the house. I believe I have approximately 50 feet from the back of the house to the pine tree so I might need shorter radials but would need more of them, if that makes any sense. I found out last night that my friend's neighbor just recently sold their old tv tower that was next to their home. Oh well, I'll keep looking. Thanks all. Gerry kd8rfo 73

Hi - While I'm studying to earn my Ham license, I'm listening now with an inverted V fan dipole about 17' high at the apex. I'm going to raise it twice as high -- about 35'.
Will I notice much of a difference in reception as far as signal strength ?
I know that height does make a difference when transmitting but until I can legally operate, I just wanted to know.
I listen mostly to 40 and 80 meters and on this small city lot, 35' is about as high as I can go .
Thanks,
Mark

Signal strength on receiving is fairly unimportant on those frequencies. External noise sources dominate, so even if the signal were quite a bit stronger or weaker, it should not make any difference in terms of reception.

On the other hand, getting the antenna away from sources of noise, that can help.

OK FOLKS:

Here are the rules of the reflector : HAM-ANTENNAS
This file will be sent once a month automatically to remind all users.

1. Name calling (race, religion, politics, gender, etc.), is prohibited.
2. Telling someone they are ignorant (in any way, shape, or form), is prohibited.
3. Denigrating other races or minorities, or expressing POLITICAL VIEWS will earn you moderation or banning.
4. If you do it privately it is a private dispute. When/if it spills over onto the reflector, you will be moderated or banned.
5. Even coming close to these boundaries is to be avoided.
6. Banning/moderation will be used, with NO notification to the transgressor.
7. Civil chatter and Civil wordage is THE rule.
8. IF the Moderators are offended, then penalties will be applied.
9. There are two Moderators, EITHER can ban/moderate you.
10. Moderators ARE the final arbitrator of disputes, we hate bickering!
11. USE Private or Direct Emails to address your concerns to the Moderators, because public postings may likely result in penalties as above. !!!!
12. Use common sense. If you would be hurt or upset if you received what you are about to send, and you are intentionally meaning to do that, DON'T DO IT!

13. We ALL would like to enjoy discussion about HAM-ANTENNAS, nothing more.

First, I have been considering either purchasing an Gap Eagle DX or a Hy Gain AV640. I was wondering if anyone in the group has owned both and what their experiences are with either, and or the benefits over other verticals for either one.

Second question, I am having significant issues with tuning my elevated 5btv at my rental home as I am very limited in term of laying down radials.

Some history, I had this antenna mounted in similar fashion, elevated with limited radials and it was tuned perfectly. I assembled exactly the same way as it was and it marked it the same with a sharpie and now everything is wide off the mark mostly much higher above the desired band for example on 20m it is at 1.6:1 at 14.900 MHz. All other bands are widely off or no where near 2:1. I wonder if the antenna was damaged due to the move. The only other difference in addition to moving the antenna was that I added the DX engineering U239 add on feature so I could connect coax directly. I have also tried two different lines of coax and added new batteries to my mfj259b to make sure it was not the culprit of giving false info.

33777. Two different values for impedance in 4nec2

Yahoo group: ham-antennas (2014)
Date: 2014-09-01 16:54:02 UTC
From: schwartzj22@...
Topic: 33777 Message: 33777

To all 4nec2 users,

If I run through the procedure below with 3.58 MHz as the chosen frequency (as seen in the Far Field Pattern results) I will get one value of impedance in the Frequency sweep for 24.917 MHz. If I repeat the procedure but the chosen frequency is now 24.917, I will get a different value for impedance at 24.917 MHz in the Frequency sweep. This shouldn't be.

1) Open file
2) Edit-Input (.nec) file
3) Calculate nec-output data
4) Far Field Pattern, Generate
5) Frequency Sweep, Generate

The antenna is a simple wire antenna-88 foot doublet.

What am I doing wrong?

Any help is appreciated,

Joel - N3GSE

I am using an Eagle One http://www.w8afx.com/ that I got after seeing it at the Shelby Hamfest last year. I now have it mounted on the awning on my back porch, and the awning seems to do OK as a ground plane; worked Mexico and Venezuela, plus Tortuga Island (Arrr!) on 15 and 20. I cheat sometimes and use an old SB-200, and often, it is just too easy... Tuner is an old Heathkit SA-2040.

However, I suggest you shine up a ground rod and drive it and a couple of others in parallel at least 4 feet at the base of the vertical. Remember also that changing locations can change everything about an antenna; for us, it is an inexact science, more of an art.

Next, start tuning the traps and sections. Your translocation has changed everything. Happy antenna work!

Hi, Joel!

My guess is that 4nec2 is changing the number of segments in the wire segments making up the antenna. This can definitely change calculated Z. Check the nseg fields in the .nec file.

Hi,
I have owned an 18AVQ, and 4BTV, in addition to a GAP Challenger... I still have the Challenger, and not the others... I like the GAP because it is a vertical dipole, and as such does not need the radial field a monopole needs, like the 4BTV, and 18AVQ.

I have a review of the GAP Challenger at:
http://nk7z.net/review-of-the-challenger-dx-antenna-by-gap-antenna/

From: Mel Farrer
Topic: 33777 Message: 33782

Hello Joel,

A couple of things. The height above ground; When some part of the antenna is less than 1/4 wave AGL the results will give you different information in gain, impedance, reactance etc. for NEC2 using Real/MININEC vs High Accuracy. In my opinion neither one like to look at antenna elements near ground. Unless they represent ground like radials. They just give you a fudge factor in the algorithm used to do the computations. Lastly, the choice of 3.8 makes one percentage of wavelength to ground and 28 gives you one that is >7 times higher AGL.

Hope that helps a little.

Mel, K6KBE

Hi Keith,

Quarter wave antennas need radials, lots of them, to make them "immune" to their mounted locations. "Everything" has changed since you have went to a different mounting location: angle of the radial, height above ground, etc, etc. Only "cure" is to tune the antenna in its present location from scratch.

My BTV is ground mounted and was adjusted using an MFJ259B. The drastic changes slowed down above 16 quarter wave 80m radials, but didn't "stabilize" until I hit the 30 to 50 range. I stopped adding radials at 54... the point of diminishing returns.

So, add some more radials and check the swr while doing so; if adding radials doesn't work, then tune the antenna band by band.

Sorry for the bad news...

Jimmie,

It is a bit remarkable to me how much the change in environment has impacted my 5btv. I began to think a little more about where the antenna was previously located. It was on a 250' canyon edge and my few radials were attached to a 220' long chainlink fence, and the antenna itself was in a concreted old five foot tall lead safe that the door was removed from. Maybe that made a difference. I didn't use the antenna much at all because I had two HF Yagis, slopers and dipoles at that QTH but now the new QTH is very limited. Maybe all that metal helped in the tuning of the 5btv.

I will keep playing with it though now I am leaning towards the Eagle since it is relatively inexpensive and doesn't seem to need radials. I guess I am luckier than many that I can have something up though I don't even have room for a full size g5rv. Amazing how change in location can impact options.

Thanks,

Keith

33786. Re: Two different values for impedance in 4nec2

Yahoo group: ham-antennas (2014)
Date: 2014-09-02 03:05:38 UTC
From: schwartzj22@...
Topic: 33777 Message: 33786

Dave,

I have segments all taken care of in the Input (.nec) file as shown below.

```
f=24.917 ........freq, MHz
hgh=13.7160 antenna height
wl=299.7892/f wavelength
sl=wl/80 ........seg length
len=26.8224 antenna length
wans=int((len/2)/sl+0.5) w1 #segs
wbns=int((len/2)/sl+0.5) w3 #segs
```

Wire 2 is the source and it is always 1 seg. All the segs for the whole antenna come out very close to the same length.

But I think you are on to something here. If I do a Far-Field Pattern and then Generate at a specific frequency then what I have done in the Input file takes place. I can check the Geometry window and all is as it should be.

But, I wonder if when I do a Frequency sweep, are all the instructions in my Input file obeyed for each of the 8 frequencies that are scanned per those I have listed in the freqs.txt file? I am not sure how to check on this. The Geometry window just shows the frequency in the upper right hand corner that is the last Far-Field Pattern that was run. It doesn’t change when I click on any of the 8 pre-determined frequencies shown in the generated graph.

Using Frequency sweep may not be a good way to go unless the instructions in my Input file are obeyed for each of the pre-determined 8 frequencies.

Thoughts?

Tks,
Joel – N3GSE

Mel,

My modeled antenna is 35 feet high and most of all my checking is at 24.917 MHz. Well above 1/4 WL. However, in Frequency sweep one of the freqs is 3.58 so this is below 1/4 WL.

At this point I am not sure where to go with this.

Tks,
Joel - N3GSE

33788. Any advice on this doublet variant?

I have recently come across the design of the "Comudipole" Doublet antenna and, if possible, would like some expert deliberation...

(Unsurprisingly, the group archives didn't reveal anything called a "comudipole".)

For those unfamiliar with the comudiople it's just a doublet, but instead of the balun (if used) being at the far end of the ladder-line at the tx end, it's at a convenient point where the coax joins the ladder-line. I doubt it's a new idea.

Like many hams, my shack is not at the centre point under the doublet, as conveniently shown in all the books, but inconveniently located at one end. Trailing ladder-line over the ground and through bushes for 25 metres isn't an option, whereas bringing the ladder-line straight down in text-book fashion and joining it to coax near the ground to run through bushes might be.

Of course the ideal solution would be a coax-fed remote ATU with balanced output at the bottom of the ladder-line (or even up at the centre of the doublet), but remote ATUs are pretty expensive, and most don't start sensing below about 5 watts - so my frequent QRP operation wouldn't be an option.

I have space for a 40m long end-to-end doublet at about 10m high at the centre. The idea of putting a balun to "match" the coax to the ladder-line seems too good to be true, although very convenient the have the ATU in the shack.

I guess it's a sort of G5RV/ZS6BKW multi-band doublet/dipole with all the nice lengths and matching thrown out of the window by rigging up whatever one had space for, bodging together the ladder-line and coax, and then just relying on the ATU, hoping none of the dimensions throw up impossible matching impedances.

So... assuming there are not too many frequencies where most of the RF goes to heating the coax (RG213) on the ground, what are the thoughts on a balun? Made from coax? Ferrite? Iron dust? 4:1? 1:1? Any chance this antenna (40m end-to-end) might work in 160m without strapping the feeders as a vertical?

The maximum power will probably be from a DX60 (or more likely HW9 or bareback K2), so were looking at say 60W PEP maximum.

Thanks.

Ian,

I have never heard of that name before but all my doublets have 450 ohm twin feed. To a 4:1 balun then 50ohm coax to the house to the back of the atu. This has worked well for me and the atu does a fine job and gets everyone below 1.5:1 I wouldn't build a doublet any other way!

Thanks to all that answered. I am planning on purchasing the Gap Eagle based on recommendations of it being a vertical dipole versus a quarter wave vertical. I am sure it is a compromise antenna regardless and don't have great expectations for it but nevertheless I am anxious to get back on the air in some form or fashion.

My 5btv I will box up and possibly ship it to my inlaws house in Texas. I already have a shack there for when I visit (RS35 power supply, 6m te systems brick, 6M7JHV, 80-10m OCF dipole, etc. inlaws are cool might as well send it there.

Thanks,

Keith

Hi Ian.
I am a doublet fan :-)
You find some good info about the Comudipole here:
http://www.rsgb.org.uk/books/extra/backyard.htm
Unfortunately, the link to the book itself does not work. But the link to fig. 3 does!
So this should be a good solution for you.
It's worth a try, but I am afraid that you will meet some challenges:
Both the length of the ladder line and the length of the "dipole" (that's what it is) are critical to get the antenna tuned on the different bands - most of all the length of the ladder line. Some inches more or less can make a big difference.
It also depends on the matching range of you tuner. The tuners that are integrated in some transceivers often do not have the necessary range. A simple manual tuner, especially from MFJ, and an external 1:4 balun right behind the tuner's coax outlet, is in general much better.
If I were you, I simply would try, and experiment a bit with the length of the feeder - if necessary.
It is much better, if you use a "real open feeder" (with spreaders) insted of ladder line, because with symmetrical ladder line feeders, you must retune if it starts or stops raining or snowing.
You can have a look at my doublet here:
http://www.qrz.com/db/LJ6BG
I use 450 Ohm ladder line, because its more convenient to install in my qth, even if I have a box with commercial spreaders in my shelves.
I made my doublet as long as my garden allows. I can tune it on ALL bands from 6 to 80 m, but NOT on top band. The minimum length for a doublet that can be used on 160 is 2 x 24 m.
I have tried that by adding a piece of wire BENDED to the ends of my doublet. Tuning is ok, but the reports were miserable. It was difficult to make contacts even with 90 watts.

I found the link to the PDF on that antenna to be especially interesting
because of the easily made 9:1 UNUN.

In my case, I want a 9:1 UNUN in order to better match the almost 4K ohm
input impedance of my WWII ARC-5 receivers.

However, my 9:1 UNUN must work from about 190 KHz through 9 MHz, so
unless someone here can quickly advise me of what changes to the UNUN
in that article must be made to enable coverage of my required frequency
range, I will have to do some more research.

Thank you for the link.

sl=wl/80 .....seg length

Here segment length (and therefore segment count) is specified
as a function of wavelength. I believe this means the same wavelength
as specified just above.

In one run, f=24.917. All the functions of f are calculated.

In another run, f=3.59. Different segment length.

Is this some scripting language used by 4Nec2?

It doesn’t change when I click on any of the 8 pre-determined frequencies shown in the generated graph.

NEC2 doesn't change your geometry when you scan as a result of the FR card.
If there are 19 segments in a wire, then there are 19 segments in that
wire, period.

Unfortunately, I cannot use 4nec2. But this is how NEC2 cores work.

How to check?

I don't know what a "freqs.txt" file is, unfortunately. It sounds like
a list of frequencies at which you are requesting a single-point "scan".

Try specifying the segment length as a constant, say .1 m.

> Using Frequency sweep may not be a good way to go unless the instructions in my Input
file are obeyed for each of the pre-determined 8 frequencies.

Depends what you mean by a "good way to go". Where were you going?

It sounds like you want segment length to change for each frequency in
a scan/sweep. ("FR card"). That's not going to happen in NEC2.

I agree with what you want -- segment length is not a physical property
of an antenna, it is just an artefact of computation, a parameter to
the MoM algorithm. Ideally, results should be independent of segment
length. In fact, Cebik wrote a relatively lucid article on this subject,
trying to obtain convergence to fixed results as he manually changed
segment length for some test antenna. I've done a half-assed job
of this since your post. It's surprising how slowly NEC2 converges.
I can see differences between 146 segments/arm and 150 segments/arm, at
15 MHz. (I'm surprised at this. Close, but no cigar.) Now there is a
limit on how many segments you can have in a wire, one due to "computers"
(depends on some internal NEC2 limit or on how much memory you have,
depending on version of NEC2, I believe), and another "silent" limit
due to "mathematics", i.e. the nature of the MoM algorithm and the "thin
wire approximation". This "math" limit is a function of the wire size.
I believe you want to have segments that are at least 4x the diameter
of the wire, or the approximation gets funky. Call it 10x. So you
can't just set your segment size to 1 mm for wire of diameter 1mm.
(NEC2 thinks of a segment as a "thin wire", but a segment 1mm long by
1mm diameter isn't "thin", it's a sort of barrel!) There's a "practical"
limit, too, namely how long you want to wait for results. Execution time
goes with the square of the number of segments. (NEC2 must calculate
the interaction of each segment with each other segment, for all the
segments.)

The theoretical size of a segment must be small enough so that replacing
the actual current in that segment (which varies continuously over its
length) by the average of its endpoints is a "valid" approximation.

I built a nice ground mounted aluminum vertical from a NOS CB antenna. Using a 4:1 UNUN it performed pretty well. Wind got it a while back and I had another identical antenna I am working on to convert it to a 10-40 antenna like the first. My question is what could I expect from this antenna if I roof mounted it, about 30 feet high? Is there a need or desire to have wire radials or could I use the solid aluminum radials as the original antenna specs. Just wondering if roof mounting would be as effective as the ground mount version? Any ideas would be a help

I own one. I also own the single-band 20m EFHW and the 40m EFHW.

I've found the 6-40 to perform reasonably well for SOTA (mountaintop) operation. I get better signal reports with the EFHW than I do with the end-fed random.

This is basically the same antenna as my Eagle One ant on my motor home. I feed mine with a home wound 4:1 un-un . I use the frame of the 31ft motor home as a ground and the ant is mounted on the ladder. It takes a 71 plus year old about 5 minutes to have it on the air . I work 75 thru 6 mtrs however 75 is better when I connect another 31ft of wire drooping down and secured to the windshield wiper blade with string . I have wasted many years of my Ham adventures on tall towers and large YAGIS . These wires are a ball ! Chuck Wq5B

33800. Roof mounted vertical antenna radial field

Yahoo group: ham-antennas (2014)
Date: 2014-09-02 18:25:32 UTC
From: Jimmie K9JFK
Topic: 33800 Message: 33800

Hi...

Walt Wilson inquired about the effectiveness of a roof mounted vertical antenna. The hard part, it seems to me, would be putting in enough radials for an effective installation.

Has anyone added radials to the underside of the roof; that is, working in the attic? Working there would be faster and safer, plus the radial wires would just need to be stapled to the supports or underside of the roof. A single wire would need a pass through to the outside of the roof, of course.

Any thoughts or experiences?.

> I guess it's a sort of G5RV/ZS6BKW multi-band doublet/dipole with all the nice lengths and matching thrown out of the window by rigging up whatever one had space for, bodging together the ladder-line and coax, and then just relying on the ATU, hoping none of the dimensions throw up impossible matching impedances.

Yeah, it's a G5RV variant. So most internet discussions of the G5RV will probably be relevant. Read G5RV's later discussions in particular.

> So... assuming there are not too many frequencies where most of the RF goes to heating the coax (RG213) on the ground, what are the thoughts on a balun? Made from coax? Ferrite? Iron dust? 4:1? 1:1? Any chance this antenna (40m end-to-end) might work in 160m without strapping the feeders as a vertical?

Well, balun "A" may be good on one band, but stink on another.

Use ferrite. Which ferrite? Depends on which band is most important.

Don't forget about losses in the balun. All pro-balun articles do, since they consider the cases only when a balun, designed to match 200:50 ohms is used with those very same Z's. All manner of baluns work OK under such conditions, even old ratty wire wrapped on an iron rod.

But casually using a balun that is fine at 200:50 at 600 : 166, or even backwards at 12.5 : 50, results in internal losses, heating the balun. Baluns often crack. The problem with this antenna is that you may well have a variety of impedances on various bands (and also over a single wide band, like 40 or 80/75). No one balun will be ideal for all bands.

You can load a 10 ft length of wire to resonate on 160m, but it will have a bandwidth as narrow as a knifeblade, or will be faking a broader bandwidth by losing power somewhere. This seems to be a fact of nature. Shorting the ladder line (and deploying a counterpoise!) turns the antenna into a capacity hat and the ladderline into a radiator. This will work "better". You'll still need to match it some how, probably a loading coil at the bottom of the ladder line. Also possible to put an L network there, matching stubs, and/or other fun things; see the book. What book? Dunno for sure.

> The maximum power will probably be from a DX60 (or more likely HW9 or bareback K2), so were looking at say 60W PEP maximum.

Yes, works great. In fact I'm happy enough with it that I'm just getting ready to do it again with a Small SteppIR vertical and the house attic.

I have used that set up with a 4 BTV on the garage roof and found no apparent difference in performance, although it does take a bit of creativity with the 40 meter radials if that attic isn't big.. In the garage I put mine across the long diagonal corner to corner in opposite directions and folded the rest of the radial along the base of the roof in opposite directions. I'm sure it must compromise things a bit, but the simplicity of not having any radials on the roof made it well worth it.

Because of the folding on a few bands, I tuned mine to resonance by tying two together and measuring like a dipole FWIW, although I've heard other opinions as to whether that's a good or bad idea.

In a message dated 9/2/2014 1:28:28 P.M. Central Daylight Time, ham-antennas@yahoogroups.com writes:

Hi...

Walt Wilson inquired about the effectiveness of a roof mounted vertical antenna. The hard part, it seems to me, would be putting in enough radials for an effective installation.

Has anyone added radials to the underside of the roof; that is, working in the attic? Working there would be faster and safer, plus the radial wires would just need to be stapled to the supports or underside of the roof. A single wire would need a pass through to the outside of the roof, of course.

Any thoughts or experiences?.

To all,

Here is another approach that would really help me.

If you have EZNEC can you model my antenna and see what you get for the load impedance? If you stay really close to my parameters then at least I can see what the correct antenna load impedance is and can proceed from there in my work. In 4nec2 I get two different impedances depending on how I set up the run. Of course this should not occur. I am sure that one of them is correct but I do not know which one is correct, yet.

88 foot horizontal doublet
35 feet high
Wireman part # 532, 18 ga silky poly material. It is polyethylene material,
0.0010541 meters-radius of insulated wire
0.00056515 meters-radius of bare wire
24.917 MHz is the freq of interest to me.
Real ground – conductivity – 0.005, diel const - 13

I provide this wire information in the event you can model insulated wire using EZNEC. If not, just use the above radius information for the bare wire.

Tks,
Joel – N3GSE

OK, it seems to be what I thought. The differing values of Z for 24.xxx MHz are due to differing segment lengths, depending on whether f in the first SY card is set to 3.xx or 24.xx. "Normal Operation", I think.

Topic: 33810 Message: 33810

I have an old TV antenna where the elements can be scaled down to 144/440 band. The original TV antenna was dual band and the UHF elements were coupled to the folded VHF dipole.

I obviously have to move and shorten the existing elements but what should be the placement of the 'driven' 440 element be in relation to the 144 dipole?

Dave,

If I run autosegmentation vs. my design without autoseg here is the result:

Auto seg
118 segs total for the antenna on 24.917
18 segs total for the antenna on 3.58

My design (no auto seg)
178 segs total for the antenna on 24.917
26 segs total for the antenna on 3.58

So I am running with about 50% more segs for my design.

So, are you saying that if f=3.58 and if I do a Freq sweep, I will only have 26 segs on the antenna at 24.917 MHz? In other words, Freq sweep will not assign 178 segs for the total antenna even though in my design it should be this number for 24.917 MHz?

Tks,
Joel - N3GSE

I have now noticed that your wire 2 (the little feed segment) changes its size depending on "sl", the calculated segment length. This in itself will cause the antenna to vary with frequency. I'd make that segment a hard constant. I like something like 20mm. Why? I dunno. There is a physical reality here, though, the distance of the gap in a "real" dipole.

I also notice that there is an error in your logic.

Consider this GW card. (also the one for tag 3):

GW 1 wans -sl/2 0 hgh -sl/2-len/2 0 hgh 0.00056515

Notice that you add sl/2 to its overall length. That's an error; it changes the total length of the antenna as a function of f, which is not what you wanted, I think. I think that GW card should be, instead:

```
GW 1 wans -sl/2 0 hgh -len/2 0 hgh 0.00056515
```

Dave,

Joel> > So, are you saying that if f=3.58 and if I do a Freq sweep, I will only have 26 segs on the antenna at 24.917 MHz? In other words, Freq sweep will not assign 178 segs for the total antenna even though in my design it should be this number for 24.917 MHz?

Dave>> Yes. Exactly.

I would like to understand this problem and be able to solve it. First, for some reason I always thought the source wire (in this case wire 2) doesn't not count as part of the length of the antenna. Am I wrong about this?

If it does count as part of the length of an antenna, how about I change my design so that wires 1 & 3 are automatically adjusted by my design to compensate for the variable length of wire 2? The total length of wires 1, 2 & 3 would always be 88 feet. Do you think this would solve the problem?

My current design is such that segment length for each of the 3 wires always comes out very close in length. Somewhere in the documentation I read that for more involved antennas and in particular wires that have sharp angles, it is very important that segment lengths for adjacent wires are not too different. This is why I did not make wire 2 a hard constant and why I thought it needs to be variable.

It is true that this example antenna in question is very simple and has no sharp angles but I developed my logic so that it could apply for all antennas I model.

In order to get the ending dimension correct (in the X dimension), wire 1 needs to add to the end of wire 2. Likewise, wire 3 needs to add to the other end of wire 2. I think I am right about this but my mind is open.

I think the critical component here is what is first discussed.

Thoughts?

Thank you for the help on this. I appreciate your effort. It is considerable.

Agreed. This is not the only group, but is one of my several groups. I am s ure it is not the group itself, but gotta start somewhere. I does it with one other group, but on three others I do not have this problem. If this is going thrrough the board, maybe someone else has had the problem and knows of a fix. This is so annoying that I am ready to qsy to a different qrg but the topics and conversations are so good and informative.

TIA

>
>
> I would like to understand this problem and be able to solve it. First, for some reason I always thought the source wire (in this case wire 2) doesn't not count as part of the length of the antenna. Am I wrong about this?

I believe so, yes. This could be easily tested.

> If it does count as part of the length of an antenna, how about I change my design so that wires 1 & 3 are automatically adjusted by my design to compensate for the variable length of wire 2? The total length of wires 1, 2 & 3 would always be 88 feet. Do you think this would solve the problem?

When you excite wire 2, you are putting a voltage across it, i.e. forcing
the antenna to have a certain voltage drop across two points, namely
the endpoints of this feed segment. Since this length will be variable
(over a 10:1 ratio, roughly), results will vary, too.

The change you propose is what I said before, the GW card for 1&3 should
run from the end of the feed segment to 88/2 feet.

The antenna you spec in your .nec has a "len" of 41.148 m. That comes
out to 135 feet. I don't know where this "88 feet" keeps coming from.

The 41m length has a resonance near 3.55 MHz. I suspect this is something
you want.

Consider a segment at the middle of one arm. NEC actually calculates
its interaction with the symmetric segment in the other arm. (and with all
other segments of course). So how far apart are those two segments?
That distance had better stay constant if we're talking about the same
antenna. So "no rubberized feed segment allowed".

> My current design is such that segment length for each of the 3 wires always comes out very close in length. Somewhere in the documentation I read that for more involved antennas and in particular wires that have sharp angles, it is very important that segment lengths for adjacent wires are not too different. This is why I did not make wire 2 a hard constant and why I thought it needs to be variable.

In this case, it meets each of the arms at 180 degrees. I hope someone else can comment here.

> It is true that this example antenna in question is very simple and has no sharp angles but I developed my logic so that it could apply for all antennas I model.

Since real antennas have real and constant geometry, so should your model. IMO.

> In order to get the ending dimension correct (in the X dimension), wire 1 needs to add to the end of wire 2. Likewise, wire 3 needs to add to the other end of wire 2. I think I am right about this but my mind is open.

You're wrong, and you're seeing the evidence. I recommend poking around www.cebik.com and see his models.

Now think about a square loop: are you going to swell the loop to accommodate a feed segment?

THink now of the feed segment. It has a voltage across it. Having a voltage, there is a current. Having a current that changes, there is radiation. Isn't that part of the antenna?

A workaround -- for this dipole use just one wire, from -len/2 to +len/2. Ensure that the number of segments is odd. Excite it at the middle segment.

> I think the critical component here is what is first discussed.

In 4nec2 for a dipole you would make (1) long wire and center the source.
That creates a dipole and the software thinks of it as 2 pieces of wire
split in the middle.
This is how I have done it and most of the examples of simple dipoles in
the examples provided with 4nec2 do it that way also.
I even do it that way with my yagi driven elements unless I'm doing
something that doesn't resemble a simple dipole.
If your doing something similar to a g5rv that is fed with ladder line
then the source isn't at the dipole so it doesn't count.

As above just create one long wire that is the length of your total
dipole in length and center or put your source where you would like it
to be such as centered or off centered. 4nec2 knows that the source is
to be where you split the wire.

If you do as was said and follow nec2 guideline your won't have a
problem with 4nec2.
There are very small differences and they will be documented in the
documentation that Arie Voors supplies
Your really should do the tutorials that he has on his site if you
haven't already.

33828. Re: [ham-antennas] Vertical questions

Yahoo group: ham-antennas (2014)
Date: 2014-09-03 10:49:02 UTC
From: Walt Wilson
Topic: 33775 Message: 33828

Lots of good information given, and I thank all of you who contributed. But on the less technical side (because most of the articles are very technical in nature) I simply wanted to know if mounting this multiband antenna on the roof would work with any decent results. I do not plan to have a lot of wire radials on top of the roof or in the attic, but I can have some aluminum radials attached to the base of the antenna.

From: mailto:ham-antennas@yahoogroups.com
Sent: Tuesday, September 02, 2014 12:56 PM
To: ham-antennas@yahoogroups.com
Subject: [ham-antennas] Vertical questions

I built a nice ground mounted aluminum vertical from a NOS CB antenna. Using a 4:1 UNUN it performed pretty well. Wind got it a while back and I had another identical antenna I am working on to convert it to a 10-40 antenna like the first. My question is what could I expect from this antenna if I roof mounted it, about 30 feet high? Is there a need or desire to have wire radials or could I use the solid aluminum radials as the original antenna specs. Just wondering if roof mounting would be as effective as the ground mount version? Any ideas would be a help

Dave,

OK on all your info.

The model I sent before should have:
hgh=13.7160 'antenna height
SY len=26.8224 'antenna length

But all else is the same and is my model that I have used for the doublet.

Sometime today I will run a one wire model with source in the middle.
That should tell us what we need to know.

Tks,
Joel - N3GSE

No. Am posting through my home mail on comcast.net. However, this problem has shown up only recently. It is funny that only two out of five have this problem. This one and N3FJP Software. I do post ham-antennas@yahoogroups.com . When I make a reply it still does the same. I have posted a test to myself, and it comes out correctly.

Maybe as suggested, this is a YAHOO problem I do have a nephew that uses this computer, that I can have try to send me a message from his msn account. (don't worry, at 32 he only uses it fro very limited purposes i.e. ebay, netflix orders, car ads).

I don't know specifics on this version of the moxon. Perhaps you can find
more info on the Moxon Project web site.
From the picture it appears to be a 17 meter moxon with a 12 meter DE
spaced about 6 inches in front of the 17 meter DE and paracitically
excited. The 12 meter DIR is in front of the 12 DE by about 3 feet, about
.1 Wave.

Hi guys thanks for the replies.

I've had a look on that website but there's nothing covering this antenna. Moxon and yagi combo for 17m and 12m.

I've use the antenna calculator for the moxon but not seen or used one for the spacing of the 12m yagi.

I think your correct, it's only fed at the 17m moxon but just an open sleeve on 12m.

Topic: 33775 Message: 33848

Walt, for my background with verticals if you mount low and have “ground” radials you need several for good performance and the do not have to be a exact length. With a raised feed point I have found you will only need 3 or 4 per band and the have to be the correct length for your transmitting frequency. I once mounted a full size 40 meter vertical 20ft high in the center of my 55x70 steel roof over my pole barn but I had to add 4 33ft radials for good performance. I am not familiar on how a 27 Mhz antenna could be used as a 28 to 7 MHz antenna without a remote auto-tuner at the base. My only 10 to 40 vertical has had traps.

Lots of good information given, and I thank all of you who contributed. But on the less technical side (because most of the articles are very technical in nature) I simply wanted to know if mounting this multiband antenna on the roof would work with any decent results. I do not plan to have a lot of wire radials on top of the roof or in the attic, but I can have some aluminum radials attached to the base of the antenna.

Subject: [ham-antennas] Vertical questions

I built a nice ground mounted aluminum vertical from a NOS CB antenna. Using a 4:1 UNUN it performed pretty well. Wind got it a while back and I had another identical antenna I am working on to convert it to a 10-40 antenna like the first. My question is what could I expect from this antenna if I roof mounted it, about 30 feet high? Is there a need or desire to have wire radials or could I use the solid aluminum radials as the original antenna specs. Just wondering if roof mounting would be as effective as the ground mount version? Any ideas would be a help

Start with "FUBAR AKA: YAHOO!"

And FREE AKA: COSTS YOU NOTHING.

If we were paying for the service, I would complain. Like HRD. If I am still running the free version, I cannot complain. If I buy the current one, and have problems, I will complain loudly.

I know we are supposed to be "paying" by having ads, but I am using Chrome with "AdBlock Plus". SO I am really getting it for free.

33851. Use of Architectrual Finial to hide 70cm vertical

Yahoo group: ham-antennas (2014)
Date: 2014-09-03 18:47:31 UTC
From: N7RJN@...
Topic: 33851 Message: 33851

I live in a community with an HOA that has some significant restrictions on installation of antennas. On the peak of my roof, there is an architectural finial made from high density polyurethane. This finial is about 40 inches high and has a 1.25 inch diameter thin walled PVC pipe down the middle that I could install a a 70cm antenna inside, thus hiding the antenna.

My question is would the high density polyurethane significantly absorb any of the 70cm radiation, thus reducing the efficiency of the antenna? Also, would this tend to change the tuning of the antenna?

I can provide a picture of the architectural finial to any one that is interested?

Thanks and 73,

Bob

Tha Gap Eagle is not cheap at $300. I have been going like crazy since I put up my Eagle One. With only about 20 feet of feed line, I do not lose much power, and using a tuner, I can tune quite nicely from 40 to 10. Price, $130.

Well I found information pertaining to this type of conversion over a year ago. Most of those trying it were using old discarded antenna's to start with. I found two NOS in the box antennas. Following the instructions I lengthened the upright with some old spare parts, eliminated the original coil in the base (wire only) and added a coax connec tor that fed the upright at the the lowest point above where it used ubolt's to attach it to a mast. I used a 4:1 UNUN at the coax attachment point, ground mounted it with about 16 wire radials and had good success with my ICOM PRO with built in tuner. After a pretty severe wind storm I found some issues and decided to take it down. While I have the "new" one still not installed, I thought I might try roof mounting it for comparison. BTW, it worked 10 through 40 meters quite well, no remote tuner, no traps

If you put a piece of it in the microwave oven and cook it on high for at least
a minute, and it does NOT heat up, then it will not cause any problems for
your antenna either.

Bob - there -may- be a difference between restrictions and enforcement.I also live in a sub-division where our CC&R's specifically say "no ham antennas". However, the HOA does not go after "minor" infractions. I'd be willing to bet that putting up a 90 foot tower would roust the troops, but some well placed, semi-hidden stealth antennas don't normally bother anyone. Of course, if you've been feuding with your neighbors - things are different! We moved into our QTH nearly four years ago. I asked the neighbors on either side of us if they'd have a problem with my stringing up some thin wire antennas. I also told them what it was for, AND if they encountered any TVI/RFI to please let me know ASAP. No one objected.

I currently have an 88 foot long doublet strung through the trees, an 80 meter Inverted L, a 160 meter Inverted L, a 5/4 wave 2 meter vertical, and a ground mounted Hustler 5BTV. I usually run 60 - 100 watts, but occasionally crank up the Elecraft KPA500 amp to 500 watts and have never had an issue. The wire antennas are made from either #26 or #22 wire and are very, very difficult to see. Granted, having a bunch of 60 foot tall redwood trees is a big help, but the wires do run between them.

Are your HOA/CC&R folks hard-nosed or do they tend to not bother with the small things?

Nope....G5RV if fed according to G5RV will be open wire feedline so you
would make 2 wires with an open wire feedline in the middle.
Then the open wired goes down the specified amount according to the
version your dealing with.
Then the source can go there or add in the coax and put the source wire
there.
Just depends on what data you want to see.

It will probably be radiolucent, however it may have an effect to the velocity of the antenna. Therefore, you may need to adjust the length of the antenna appropriately to correct for the new velocity factor.

Bob,
You might also look at the Ventenna, which is designed to look like an exhaust vent mounted on your roof. I have read on the other sites that some hams have taken the idea and adapted it. Nothing is better than being able to hide something in plain view.

My HOA are sticklers as well. I got my licence last Jan. and have not yet figured out a permanent solution for my place. Keep at it.

Bob..

Another solution would be a flagpole. Your HOA may say no, but it is unenforceable. The courts will not rule against someone flying the American Flag. Famous SCOTUS ruling there that stemmed from a Vet in Florida, who wanted to fly a flag, on a pole..HOA said no, the coursts ultimately said yes. (The fact he was a MOH awardee helped his cause!)

A quick check online only yields answers from companies treating their polyurethane foam with graphite to make intentional RF absorbers.

I did not have any luck finding the cross-section of architectural polyurethane foam.

Polyurethane without any contaminants intended to absorb RF should have properties similar to any other insulator. Just as insulation on wires affects the tuning, I would expect foam around the antenna to affect the tuning.

If you have free or cheap access to both the antenna and the finial, this looks like a time for some experimentation. If you can identify the characteristics of the finial material, you might find the same material in another form factor at a price that encourages experimentation. PVC is used in many instances to protect antennas, so I would not expect significant problems from the internal PVC tube, unless it is also treated.

Nope it's 4nec2.

Dale,

OK. I always did the 4nec2 model without a TL then used TLW3 for the rest of it.
More to check out.

Tks,

The best test would be if you could get an identical finial and try the antenna in and out of it without having to climb up on the roof or even in a blazing hot attic. Not that I would ever suggest it, but you could always return the item after testing, or just keep it as a spare.

Regardless of what many/most people say, PVC does have a blocking effect on RF. Maybe not at UHF frequencies, I can't remember. They use HF in factories to soften/melt PVC because it absorbs RF at those frequencies. Usually they use 27.120 MHz so I'd say that PVC would be a poor choice for enclosing a 10m antenna.

Testing material in a microwave will only tell you if that material will absorb RF in the vicinity of 2.45 GHz, which is what the oven is using to warm food. That's quite a way off from 440MHz...

---In ham-antennas@yahoogroups.com, <N7RJN@...> wrote :

I live in a community with an HOA that has some significant restrictions on installation of antennas. On the peak of my roof, there is an architectural finial made from high density polyurethane. This finial is about 40 inches high and has a 1.25 inch diameter thin walled PVC pipe down the middle that I could install a a 70cm antenna inside, thus hiding the antenna.

My question is would the high density polyurethane significantly absorb any of the 70cm radiation, thus reducing the efficiency of the antenna? Also, would this tend to change the tuning of the antenna?

I can provide a picture of the architectural finial to any one that is interested?

Thanks and 73,

Bob

Pvc can be used for uhf ... and for 10m also

.... I worked in a plastic company (we made tent materials and similar things) ... or in other words plastic on woven fabric

For melting them together we use 1.5kw (2 big power tubes) with two electrodes and the pvc material clamped in between them (forming the dielectric material in a cap

Yes there are losses ... but 1.5kw on a few square inch ... no wonder the pvc melted in seconds

Antenna covered in a tube is a different thing

I would just try it out

If antenna in the tube works (and fits the view) the better use this as no antenna at all

I would hide a vhf uhf antenna in a vent tubing on the roof

And install a flagpole with remote tuner (maybe with an extension wire at the top for lower bands)

That would be most bang for the buck and is "nearly" invisible (so should not upset hoa)

Rather than asking the question of whether or not the finial will attenuate your signal, maybe the better question is, "Will the finial attenuate signal more than the improvement I'll gain by moving from an indoor antenna to one in the finial?" Or maybe the better comparison is between the finial and your attic.

That is a question which can only be answered by trial and error. Even a bad antenna is better than a worse antenna.

PVC is not a good choice for any high power RF field. On another world I did a lot of manufacturing with all kinds of plastics and PVC was one of the first we rejected for any high RF field. In HF 3.8 MHz 1 KW will cause a fire in the material, not in the current field but in the higher voltage area like a supporting standoff up on a vertical personal experience. Now low power VHF/UHF and if the antenna is spaced away from direct contact, I would suggest you would not be able to easily measure the loss. Ala the Ventanna for Vhf/UHF use.

Kevin,

Thank you for your comments. Neither an indoor nor an antenna in the attic will work at my QTH. The house is stuccoed so has “chicken wire" in the outside walls. Also the entire roof has an aluminum radiation barrier for energy efficiency.

One additional issue at my location is that I need to get the antenna at the peak of my roof, because there is a large hill (actually a small mountain) between my QTH and the repeaters.

As long and the bottom radiating portion of the antenna is above the roof level in other words in the clear of the roof surface you should be fine. Go for it.

Are you allowed a satellite dish for TV reception?

I was on the board of directors for a condo association here in Connecticut. We could not deny the installation of a satellite dish. Could you incorporate a stealth ham antenna on the same mount as the satellite dish? The mount would be there, so you would not be adding any additional mount for the ham antenna and the coax could follow the same run as the TV cable. Maybe a dual band mobile whip?

As a director I can say that we never really actively policed for violations. The only time we would take action would be an association liability situation or a resident complaint. We let sleeping dogs lie.

Assuming you a going to use a small vertical antenna, it would be better to put one temporarily on the roof and see if you can connect to the repeaters. If not you will have trouble unless you have a bigger antenna

If the finial doesn't work out, here's another idea. Maybe you could disguise it as... an antenna. Hear me out!

Since it is VHF, your elements will be short. You could take a plastic box, put an alarm company sticker on it, and mount it on a gable vent. Run a 1/4 wave stiff wire out the top and another out the bottom. You have a vertical dipole. If anyone asks, just mutter something about wanting your alarm system to work if the phone line is cut. But no one is going to ask because they'll just assume it is part of your burglar alarm.

If you live in a neighborhood that's snooty enough to prevent ham antennas, surely *everyone* has a burglar alarm.

33878. RE: [ham-antennas] Vertical questions

Yahoo group: ham-antennas (2014)
Date: 2014-09-04 00:54:48 UTC
From: Richard Schmuke
Topic: 33775 Message: 33878

I am curious about this set up. I have built many verticals, J-Poles and slim jims, from 440Mhz to 3.5MHz and all different types of baluns, 1:1, 2:1 and 4:1 and have always tried for a resonate antenna for maximum power transfer. What type of SWR readings do you get with the antenna, readings without a tuner? What is the basic vertical length of you antenna? If you eliminated the coil in the base was it a 5/8wl vert, about 21ft before your change?

Rich, kd0zz

From: ham-antennas@yahoogroups.com [mailto:ham-antennas@yahoogroups.com]

To: ham-antennas@yahoogroups.com
Subject: Re: [ham-antennas] Vertical questions

Well I found information pertaining to this type of conversion over a year ago. Most of those trying it were using old discarded antenna’s to start with. I found two NOS in the box antennas. Following the instructions I lengthened the upright with some old spare parts, eliminated the original coil in the base (wire only) and added a coax connec

tor that fed the upright at the the lowest point above where it used ubolt’s to attach it to a mast. I used a 4:1 UNUN at the coax attachment point, ground mounted it with about 16 wire radials and had good success with my IC

OM PRO with built in tuner. After a pretty severe wind storm I found some issues and decided to take it down. While I have the “new” one still not installed, I thought I might try roof mounting it for comparison. BTW, it worked 10 through 40 meters quite well, no remote tuner, no traps

Sent: Wednesday, September 03, 2014 1:44 PM

To: ham-antennas@yahoogroups.com

Subject: RE: [ham-antennas] Vertical questions

Walt, for my background with verticals if you mount low and have “ground” radials you need several for good performance and the do not have to be a exact length. With a raised feed point I have found you will only need 3 or 4 per band and the have to be the correct length for your transmitting frequency. I once mounted a full size 40 meter vertical 20ft high in the center of my 55x70 steel roof over my pole barn but I had to add 4 33ft radials for good performance. I am not familiar on how a 27 Mhz antenna could be used as a 28 to 7 MHz antenna without a remote auto-tuner at the base. My only 10 to 40 vertical has had traps.

Subject: Re: [ham-antennas] Vertical questions

Lots of good information given, and I thank all of you who contributed. But on the less technical side (because most of the articles are very technical in nature) I simply wanted to know if mounting this multiband antenna on the roof would work with any decent results. I do not plan to have a lot of wire radials on top of the roof or in the attic, but I can have some aluminum radials attached to the base of the antenna.

To: ham-antennas@yahoogroups.com

Subject: [ham-antennas] Vertical questions

I built a nice ground mounted aluminum vertical from a NOS CB antenna. Using a 4:1 UNUN it performed pretty well. Wind got it a while back and I had another identical antenna I am working on to convert it to a 10-40 antenna like the first. My question is what could I expect from this antenna if I roof mounted it, about 30 feet high? Is there a need or desire to have wire radials or could I use the solid aluminum radials as the original antenna specs. Just wondering if roof mounting would be as effective as the ground mount version? Any ideas would be a help

From: Martin A Flynn
Topic: 33851 Message: 33879

Perhaps a 4" x 4" Outdoor Bell box with a blank cover (RAB 5333-0 as an example) with an NMO whip antenna, along with the alarm vendor sticker?

If the finial doesn't work out, here's another idea. Maybe you could disguise it as... an antenna. Hear me out!

Since it is VHF, your elements will be short. You could take a plastic box, put an alarm company sticker on it, and mount it on a gable vent. Run a 1/4 wave stiff wire out the top and another out the bottom. You have a vertical dipole. If anyone asks, just mutter something about wanting your alarm system to work if the phone line is cut. But no one is going to ask because they'll just assume it is part of your burglar alarm.

If you live in a neighborhood that's snooty enough to prevent ham antennas, surely *everyone* has a burglar alarm.

From: Walt Wilson
Topic: 33775 Message: 33885

Exactly correct on the height, before was 5/8 wave, 21 feet, after mods it was about 27 feet. Readings were 10 meter 1:1 swr, 15 was 2:1, 20 2:1, 40 was 2:1 before using the internal tuner. Not bad without the tuner. I will be checking everything before I try to mount it on the rooftop to be certain of all settings

Subject: RE: [ham-antennas] Vertical questions

I am curious about this set up. I have built many verticals, J-Poles and slim jims, from 440Mhz to 3.5MHz and all different types of baluns, 1:1, 2:1 and 4:1 and have always tried for a resonate antenna for maximum power transfer. What type of SWR readings do you get with the antenna, readings without a tuner? What is the basic vertical length of you antenna? If you eliminated the coil in the base was it a 5/8wl vert, about 21ft before your change?

Rich, kd0zz

Subject: Re: [ham-antennas] Vertical questions

Well I found information pertaining to this type of conversion over a year ago. Most of those trying it were using old discarded antenna’s to start with. I found two NOS in the box antennas. Following the instructions I lengthened the upright with some old spare parts, eliminated the original coil in the base (wire only) and added a coax connector that fed the upright at the the lowest point above where it used ubolt’s to attach it to a mast. I used a 4:1 UNUN at the coax attachment point, ground mounted it with about 16 wire radials and had good success with my ICOM PRO with built in tuner. After a pretty severe wind storm I found some issues and decided to take it down. While I have the “new” one still not installed, I thought I might try roof mounting it for comparison. BTW, it worked 10 through 40 meters quite well, no remote tuner, no traps

Sent: Wednesday, September 03, 2014 1:44 PM

To: ham-antennas@yahoogroups.com

Subject: RE: [ham-antennas] Vertical questions

Walt, for my background with verticals if you mount low and have “ground” radials you need several for good performance and the do not have to be a exact length. With a raised feed point I have found you will only need 3 or 4 per band and the have to be the correct length for your transmitting frequency. I once mounted a full size 40 meter vertical 20ft high in the center of my 55x70 steel roof over my pole barn but I had to add 4 33ft radials for good performance. I am not familiar on how a 27 Mhz antenna could be used as a 28 to 7 MHz

antenna without a remote auto-tuner at the base. My only 10 to 40 vertical has had traps.

Subject: Re: [ham-antennas] Vertical questions

Lots of good information given, and I thank all of you who contributed. But on the less technical side (because most of the articles are very technical in nature) I simply wanted to know if mounting this multiband antenna on the roof would work with any decent results. I do not plan to have a lot of wire radials on top of the roof or in the attic, but I can have some aluminum radials attached to the base of the antenna.

Subject: [ham-antennas] Vertical questions

I built a nice ground mounted aluminum vertical from a NOS CB antenna. Using a 4:1 UNUN it performed pretty well. Wind got it a while back and I had another identical antenna I am working on to convert it to a 10-40 antenna like the first. My question is what could I expect from this antenna if I roof mounted it, about 30 feet high? Is there a need or desire to have wire radials or could I use the solid aluminum radials as the original antenna specs. Just wondering if roof mounting would be as effective as the ground mount version? Any ideas would be a help

Kevin,

That’s a great idea. In my situation it won’t work as well since I need to get the antenna as high as possible, without drawing undo attention. The final is mounted on the highest portion of my roof, so it is the ideal location, from a height standpoint.

One aspect of my location and the reason for getting as much height as possible is that there is a large hill in the line of sight between my QTH and the repeaters I am trying to hit. I currently get reasonably good results on 2 meters with my existing Ventenna, but performance on 70cm is poor.

Thank you and 73,

That is a great idea.

Don,

Thank you. I have an existing Ventenna, but is not at the highest point on my roof. It does an acceptable job on 2meters, but is nearly useless on 70cm. I did a test with the Ventenna temporarily next to the architectural Final, and 70cm was significantly better. I was able to hit the two repeaters I needed to with full quieting, so I am sure my camouflaged finial antenna will do a good job.

Joe,

My existing antenna is a Ventenna. Works reasonably well on 2 meters, but performance on 70cm is poor. I tried the Ventenna temporarily mounted next to the architectural final, and it work well on 70cm. The finial is at the highest point on my roof, so using the final to camouflage an antenna is probably my best solution. It is the highest point on my roof and is acceptable to the HOA, as it will look like all of my neighbors finials.

From: Richard Schmuke
Topic: 33775 Message: 33892

Very impressive numbers. I don’t understand how it works but there is a lot I don’t understand in life.

Please carry on and let us know your results with is raised.

Rich, Kd0zz

Subject: Re: [ham-antennas] Vertical questions

Exactly correct on the height, before was 5/8 wave, 21 feet, after mods it was about 27 feet. Readings were 10 meter 1:1 swr, 15 was 2:1, 20 2:1, 40 was 2:1 before using the internal tuner. Not bad without the tuner. I will be checking everything before I try to mount it on the rooftop to be certain of all settings

33893. Re: Vertical questions

Yahoo group: ham-antennas (2014)

From: Dave Rickmers
Topic: 33775 Message: 33893

My full wave loops are uniformly 2.5 to 3:1. A 43' vertical needs a tuner or a balun to get closer to a match, an autotuner at the feed point is ideal. See my QRZ page. 73 de dave/kd6il

33894. might this work?

Yahoo group: ham-antennas (2014)
Date: 2014-09-04 15:18:13 UTC
From: dalecole3502@...
Topic: 33894 Message: 33894

Might this work? I have a length of 300 ohm wire, which I can get up to about 30' +/- and run to a height of about 20'. (sloped of course)
If I cut this at about 66' on th run, and then divided the wire at about 33' and doubled that portion (the divided part) back upon it's self, and led it back to the feed point and into a tuner, could I effectly construct an 80/75 meter wire antenna? At the tuner I would use one of those pigtails that convert balanced wire to coax. From the tuner, Which would be located in the garage, through the wall I would use the tuner for 75 only once adjusted I have small lot, and trap verticals for other bands.

I would only be running 100w (into solid state). Might it work, or just make a 40 meter dipole, or even worse have my rig go up in smoke?
Dale K8TS

It looks like my first response did not make it. I am trying again.

You might try repurposing a Dish TV antenna into a slot antenna. Here is a link to how someone made a 2m antenna from a Dish: http://w6nbc.com/articles/20xx-dishslot.pdf http://w6nbc.com/articles/20xx-dishslot.pdf

There is a good video on how slot antennas work:
Slot Antenna http://www.antenna-theory.com/antennas/aperture/slot.php

http://www.antenna-theory.com/antennas/aperture/slot.php

Slot Antenna http://www.antenna-theory.com/antennas/aperture/slot.php The slot antenna is studied. The basic principles of slot antennas are presented, along with design parameters.

View on www.antenna-theory... http://www.antenna-theory.com/antennas/aperture/slot.php
Preview by Yahoo

It describes how the slot dimensions are roughly equal to the dimensions for a wire dipole. You should be able to change the slot dimensions for 70cm.

You are using almost a Twin lead Marconi antenna concept. A folded Marconi using 300 ohm ladder line shorted at the end can be fed directly with 50 ohm coax with the shield tied to a ground at the feed point. 234/fMHz for the length of 300 ohm line. I have used it effectively in a HOA environment under the eves of the roof. An interesting trick is that you can open the ground return side of the 300 ohm and it is 10-15 ohm impedance but resonant match at half the freq. I had to use a tuner for that but if cut for 7.2 MHz you get 3.6 when open. Not a outstanding antenna, but simple. You can see the reference of the antenna in Bill Orr's Radio Handbook in General purpose HF antennas.

Hi All,

I need a 40-20-15-10 Meter multi-band antenna. My Roof is the only place where I can instal it.
The roof dimension is 50 Feet X 15 Feet. I dont have access to masts longer than 20 Feet.

Please suggest me an Antenna that suits my space requirement, easy to build, low cost, & Easy to repair (Monkeys and Cyclones are common here).

Hi Mel,

Thanks for help.
House is a Reinforced Cement Concreted house, Height from Ground Level is 30 Feets. Both sides of house are open Grounds, but extremely Theft-Prone, so can not use wire radials upto that. Anything should must have to bounded inside the roof boundary.

No, only 2 Corners are useable on Front Side.
I tried Inverted Vee Dipole Antenna, but anyhow 40 Meter band does not fit for my roof.

Regards
Guru

How about a Hustler 6-BTV with radials laid atop the roof? That gets you the bands that you want and keeps the radials up out of harm's way.

Just a thought!

Good luck,

I've never seen a free version of the antenna comparisons you are looking for.
However, I've seen ads for just such a comparison from Steve K7LXC.
I've heard it is pretty good but maybe slightly outdated now as it was done when he had access to an
antenna range 10 years or so ago.
He probably did a lot of work doing this and I can understand why he would like to get paid for it. You can find an ad for it in
classified section of QST or CQ about every month.

You could build the G3TXQ version cobweb which would give you 20-10m, and add on a 40m element (fed separately from the rest). It would not require a tuner for any of the bands.

A half size G5RV fed with twin feeder all the way from ATU to the centre of the antenna. Effectively it then becomes a doublet. This makes an excellent multi band antenna with low losses and high efficiency.

Thanks Mel,
Seems like this will fit into my roof. Anyway, I was trying today, a vertical with a loading coil, no problem in Tx, but somehow it was huge noise in Rx with my QRP BITX on 40 Meter.

Anyway, the latest development is that, loading coil arrangement can also fit into my roof in Inverted Vee I built earlier. And making some traps to resonate at required frequency, this was suggestion by a local HAM. So I would stick to the modification of that Inv Vee this weekend. In case failure, will start with OCF dipole.

I am using a trap inverted V. It is based on half of a W3DZZ.
My vertical section is 40 foot, although you can have it shorter and it still works well.
In that case you will have a longer horizontal section.
Based on the W3DZZ the total length is 54 foot. I have now put an 80 metre trap at the end and it now covers 160.
all the best

Do not even let that slow you down!
I use to live in Oxbow estates just south of Payson, Arizona. on the NORTH side of a mountain, I was at least 300 feet below the top of the mountain.
All of the TV stations were in Phoenix AZ 104 miles south of me behind 2 more mountain ranges.
I wanted TV and this was before Primestar or Direct or Dish.
I put up an antenna and tried like mad to get a weak bounce off of the higher mountains north of me some as high as 7000' within 30 miles.
Could not get a bounce of any type so tried from West through north to East.
Not a thing, so as a last resort I turned the ant SOUTH directly into the mountain 30 feet from my antenna and received a slightly snowy but very useable picture and sound on Channels 3, 5 8, 10, 12.
All of the major networks and PBS plus an independent.

Do not tell me that radio signals do not follow the curve of the earth when they want to, *try it before you say IT WON'T WORK!*

Adrian,

That is a very good point. You are correct, RF doesn’t always seem to follow the rules. I believe that is why I do hit some of the repeaters that are on the White Tank mountains about 20 miles from my QTH. There are three repeaters that I can hit right now, but not necessarily with full quieting. Several others I can hear, but I can not hit the repeater when I transmit. Each of the repeater antennas are at slightly different locations and different altitudes. The knife edge effect may be coming into play here for some of the stations.

I bought the Gap Eagle DX and then decided that I didn't have enough time to put it up this weekend so I decided to play around with the 5BTV. I changed the position of the radials and added a few more radials and got 15m to tune about 1.5:1 mid band and 10m to tune at 2:1 at 28.100. 20m is still way off!!! I can't even find a dip and 40m is like 3:1. So getting better but still not great.

Keith

>>
>> Second question, I am having significant issues with tuning my elevated 5btv at my rental home as I am very limited in term of laying down radials.
>>
>> Some history, I had this antenna mounted in similar fashion, elevated with limited radials and it was tuned perfectly. I assembled exactly the same way as it was and it marked it the same with a sharpie and now everything is wide off the mark mostly much higher above the desired band for example on 20m it is at 1.6:1 at 14.900 MHz. All other bands are widely off or no where near 2:1. I wonder if the antenna was damaged due to the move. The only other difference in addition to moving the antenna was that I added the DX engineering U239 add on feature so I could connect coax directly. I have also tried two different lines of coax and added new batteries to my mfj259b to make sure it was not the culprit of giving false info.

Take your Meter, and measure R, every time you double the radial count, you should see R go down, when it stops, (or moves very little), with the next doubling of radials, you are done... In a perfect world you will end at 36 ohms, and have close to a 2:1 SWR.

I am spot on for 10 & 15m now and about 500 kHz too high on 20m. I have adjusted both the trap and antenna length and adjusted the trap with no difference after about 500 khz (originally the dip was at 15.4 MHz). Now the dip is at 14.8-9 MHz. I am guessing that with more radials added for 20m (I have two so far) I may see more benefit. This is an elevated mounting at 4' right now on an MFJ 1919ex tripod.

Thanks for all the help!!!

All bands on the 5BTV are now tuned for low swr under 2:1. The elevated nature is tricky as there seems to be some intermittent changes in swr. I am wondering if my coax is suspect.

I did work multiple stations in Japan on 20m last night on the 5btv with 10W SSB with my KX3. I was very surprised that they actually could hear me. I haven't been on the bands in over two months so it was quite nice to be on yesterday.

33935. BVO 18 rope yagi for 6 meters???

Yahoo group: ham-antennas (2014)
Date: 2014-09-07 20:42:39 UTC
From: Ray, W4BYG
Topic: 33935 Message: 33935

Was just perusing VE7VQH's excel SS on a number of manufactured 6 meter antennas, etc. The highest antenna gain was listed for a "BVO 18 Rope Yagi" at 15.01 dbd gain. That's a lot of gain for a yagi at 6 meters.

Never heard of one. Did a search and couldn't find any data or pictures of one. I've probably got 3 dozen books on antennas and related designs. Nothing on such as I can recall.

I'm curious. Does anyone know anything about this antenna?
73,
Ray, W4BYG

That is insulting the animals in the national parks to compare them to the feral punks in the hood.

KB2GF - Bill,

After reading of the RF ground radial conversation, I wanted to inquire of you Bill the following;

We have a Yahoo Group devoted to RF Ground Radials. Our members all share great interest regarding RF Ground Radials...Anything and all about Ground Radials!

I have read this specific thread with great interest and wanted to request of you if I may share your invitation to share your Ground Radial findings as you had mentioned.

I believe some of our group members would be interested in your findings!

I wanted to offer my respect and inquire from you, rather than simply re-post your message.

Thank you Bill, you can post reply here, I should catch it, or reply at rossradio @ wowway.com, or on the Yahoo RF Ground Radial Group at:
https://groups.yahoo.com/neo/groups/groundradial/info
https://groups.yahoo.com/neo/groups/groundradial/info
Our ground radio group is a non restricted Yahoo group.

Thanks Again, With Kind Regards...
Ross KB8NTY

From: Gary@...
Topic: 33942 Message: 33942

Hy Guys.

After 20 years I decided to rebuild my HyGain 18ht hy-tower. I've done it according to the manual. My 2 questions are:

1. Is there a sequence of adjustment eg. 10 meter first the 15 meter resonator, etc.?

2. What element resonates at 20 meters? (The only thing I can come up with is the distance between the base of the antenna and the top of the 15 meter resonator is 1/4 wave to 20 meters.) Any help would be appreciated.

33945. Non permanent antenna U bolt mount

Yahoo group: ham-antennas (2014)
Date: 2014-09-09 12:03:26 UTC
From: Keith Heimbold
Topic: 33945 Message: 33945

I am putting up a five 4' military aluminum masts with the M2 6m loop antenna at the top and want to use a non permanent / non penetrating mount on the wooden eave of the house I am renting. The antenna weighs less than two pounds and has very little wind load. Any thoughts or ideas.

Btw, I decided that since I have the 5BTV now tuned I am taking back the Gap Eagle DX I bought at HRO. I was able to make plenty of DX contacts with the hustler and would rather put that money spent towards something more interesting than another compromise vertical. Maybe I will regret it, maybe not. Been looking at the foldingantenna.com hex beam like portable antenna sold in the US by vibroplex or figuring out a way to homebrew one. It is a pretty cool potential option for me in a ham world where everything needs to be mounted portable and taken down after every use.

Thanks Bill for the manual, the one I have does not have that first page. I rebuilt the 18 HT exactly with the dimensions put forth in the manual. I have approximately 40 radials from 10 feet to 65 feet. I ran the antenna through my Rigol TG 815 spectrum analyzer. I put the results in the Files section of this group. As you can see the majority of the bands are too low in frequency, hence too long, with the exception of 80 meters. If I subtract from the center section to bring 20 meters backup from the 13.36 MHz where the peak is now, 80 meters will have its peak in the CW portion . I guess what I'm saying is it's a good thing I have a terrific antenna tuner.

Try using wood spring clamps for wood clamping, or metal 'c' clamps,
sttach the antenna to them and them
clamp them to the gutter etc.

I talked with the engineer at HYgain and he said that 40 15 and 10 meters are adjustable. 80 and 20 meters are a trade off. You can get a good match on 80 and 20 is poor. So I'm going to get a match on 20 and use my 160 loading coil with extra taps for 80.

From: Art Nienhouse
Topic: 33950 Message: 33950

*/I ran a coil across the feed point on my Hy Tower like the butternut vertical, this helped the match issue 20 meters 80 meters.
I also built up a air core roller inductor that I tuned from the shack for 160 attached are some pictures.

The coil in the picture across the feed was after trial and error (I think it was 18 turns on 1 1/2 coil form) and was a compromise for 40 80 and 160 a stepper switch with tapped coil would have been perfect. But I did not have any problem with the fixed coil as it got close on 160 under 2:1 swr in all operating spots. I could operate all the bands with out a tuner ...how ever touching it up with a tuner helped the band width on 160 buy just a bit, the motor is a 60 rpm I counted the seconds as it moved to the spot I wanted to operate them made a note so moving the vfo was made easier.

The addition of Aluminum Gutter guard really put the impedance low and was what I think icing on the cake. I had about 1500 ft of # 14 THHN wire cut 66 ft stapled to the ground they were bent around with the cold water pipes in the house attached as well.The Gutter Guard was what put it right as to enough radial system.

I changed out the metal trays to polyethylene so there was no possible arcing over on 160, I could work anything I could hear on 160 it was really surprising good performer however no band width. The big coil is an early MFJ from there big tuner it never failed much to my surprise you could run full legal power.

The coil is inside the 4 " thin wall pvc sewer pipe you see at the base of the 80 / 20 meter wire on many 40 meter dx stations the Hy Tower did as well as my C4 force rotating dipole at 65 ft. the only thing is hears a lot of vertical noise as you well know.

Best vertical ever built it also loads and works 6 meters which was a surprise to me, I used a tuner for the warc bands.
I moved to Paris Tn going on 4 years this December but never put it up here much bigger yard but not smooth, I don't think the radials will live under the Zero Turn Toro all the radials would have to be burred several inches, so its in my garage what a shame be nice if it was installed I'm just not up to the work putting it up right.

I would mount it on the Ground ,fill a 5gal bucket with quick crete bury it with mounting pipe in it to set your Aluminum masts in , then you can remove it whenever you move easily no attaching to building this should work for a short mast set up like yours . Your landlord would appreciate it as well cause clamps can do some damage and dents. Soil can be just pushed around ! hihi. Enjoy all, 73s, AJ W5HEH

I used to rent myself many years ago. I'd guess your landlord would care less about a hole in the yard than something attached to the house that could potentially damage the house's eaves and paint.

About the 5 gallon buried bucket... and its future removal. The buried concrete is a great idea. But it's removal sounds good in theory only. Removing it easily once in the ground? Not so easy. The problem is that a 5 gal bucket of concrete weighs about 300 lb! Good luck pulling that back out of the ground. Ever tried to pull a fence post up out of the ground that is set with just a single 80 lb bag of Quikrete once it has settled for a couple of days? Takes a huge amount of rocking and considerable digging. It's back breaking. Can't imagine trying to pull 300 lb of concrete up without digging around it 180 degrees, breaking it first, tilting it over and pulling it up in pieces. And if in a bucket, you can't break it. Why not just leave the concrete and cover it with dirt? It's cheap.

But just sitting a 5 gallon bucket with 300 lb of concrete in it with such a light load on the ground should work fine, depending on how tall the mast is. But that doesn't get the 6M loop above the eaves.

For perspective on wind loading, a 20' flagpole requires a hole a couple foot across a minimum of 18" deep to keep it from listing over time. But it has a heavy wind load of course if it has a couple flags on it. A typical un-guyed 25' vertical, like a Butternut, only needs a post hole dug and a single 80 lb. bag of premix to keep it from listing over time due to its relatively light wind load. I like the single post hole arrangement for such verticals. You can mount a mast/antenna in a sleeve in the hole, fill with concrete and top off the last few inches with soil. Then when you are ready to move, you pull the antenna up out of the sleeve (insure you put anti-seize in the sleeve when it was installed) and cover it with dirt. The only thing lost is the concrete and the sleeve. If you put up something with more top load/leverage with a larger mast pipe than a typical 25' vertical, then you just make the hole larger in diameter and a touch deeper. You don't need to use a sacrificial sleeve on the mast; I would just consider the bottom mast set in the concrete sacrificial and simply cut it off at the concrete when you move. Just buy a new mast pipe and consider it part of the cost of moving, or live with it 2' shorter. Or sleeve it if you like when installed.

Like W5HEH suggests, I'd surmise that a hole the size of a 5 gallon bucket (about 1' in diameter") with a 20'- 1" mast in it with that tiny 6M loop in it would stand vertical for many years, if you could get away with it by your landlord.

73,

Scott AC8DE

How much does a 5 gallon bucket of concrete weight?
depending upon the type of concrete and the mix rate, a gallon of
concrete weighs anywhere from 17-20 lbs. So 85 to 100lbs plus the weight
of the bucket.

from:
http://wiki.answers.com/Q/How_much_does_a_5_gallon_bucket_of_concrete_weight

I can carry a 5 gallon pail of water, dirt or bricks all over the
place and I can even carry my XYL around and I'm 72.

I have a 5 gallon bucket filled with concrete on my deck which I use as an umbrella stand (it has two carrying handles and a PVC tube embedded in the concrete).

While it is certainly heavy, it weighs nowhere near 300 lbs. I'd guess 85-100 lbs. at most. I can move it around reasonably easily.

"And if in a bucket, you can't break it. Why not
just leave the concrete and cover it with dirt? It's cheap."
The last line of the original message is easy to
accomplish, takes very little work. see below:

I have done this, more or less, by digging a
hole, putting a pole in the hole,(makeing sure it was vertical)
and then filling the hole with concrete up to
about 8" from the grass level. When finished, it will be sturdy, and
support an antenna, and when you Leave the rental
house, dig out the sod and dirt 8" down to the concrete, use a
circular saw with a metal cutting blade to cut
off the pole, now it's below ground level, and fill in the dirt and sod.
You'll never know anything was there in a couple
weeks, ir you keep it watered so the sod regrows.

I doubt you ever pull it from in the ground though. I would like to see the man that could pull a 5 gallon bucket buried in the ground and then filled with concrete and left for a year or so . The fence post is a good example . Chuck Wq5B

Or you might consider home brewing something like the commercial flat roof mounts, that have a platform and a bit of a
tripod, and would allow you to stack bricks or bags of sand or whatever on the platform. I've done this with a 7 ft tripod that bolts to a plywood deck and had it work well.

Woops! You are right. I made a math error. It's more like 100 lb. Still, it's going to be difficult to pull from the ground.

How much does a 5 gallon bucket of concrete weight?
depending upon the type of concrete and the mix rate, a gallon of
concrete weighs anywhere from 17-20 lbs. So 85 to 100lbs plus the weight
of the bucket.

from:
http://wiki.answers.com/Q/How_much_does_a_5_gallon_bucket_of_concrete_weight

I can carry a 5 gallon pail of water, dirt or bricks all over the
place and I can even carry my XYL around and I'm 72.

The difficulty is the potential damage to the house and how the landlord views this. The landlord could evict you for doing this is he wanted to. It won't make him happy regardless. I know if I owned the house, I would not be pleased if my tenant didn't get approval beforehand. I'd never approve anything on the roof due to the potential of breaking the seal of the roof system.

About the 5 gallon buried bucket... and its future removal. The buried concrete is a great idea. But it's removal sounds good in theory only. Removing it easily once in the ground? Not so easy. The problem is that a 5 gal bucket of concrete weighs about 300 lb! Good luck

pulling that back out of the ground. Ever tried to pull a fence post up out of the ground that is set with just a single 80 lb bag of Quikrete once it has settled for a couple of days? Takes a huge amount of rocking and considerable digging. It's back breaking. Can't imagine trying to pull 300 lb of concrete up without digging around it 180 degrees, breaking it first, tilting it over and pulling it up in pieces. And if in a bucket, you can't break it. Why not just leave the concrete and cover it with dirt? It's cheap.

But just sitting a 5 gallon bucket with 300 lb of concrete in it with such a light load on the ground should work fine, depending on how tall the mast is. But that doesn't get the 6M loop above the eaves.

For perspective on wind loading, a 20' flagpole requires a hole a couple foot across a minimum of 18" deep to keep it from listing over time. But it has a heavy wind load of course if it has a couple flags on it. A typical un-guyed 25' vertical, like a Butternut, only needs a post hole dug and a single 80 lb. bag of premix to keep it from listing over time due to its relatively light wind load. I like the single post hole arrangement for such verticals. You can mount a mast/antenna in a sleeve in the hole, fill with concrete and top off the last few inches with soil. Then when you are ready to move, you pull the antenna up out of the sleeve (insure you put anti-seize in the sleeve when it was installed) and cover it with dirt. The only thing lost is the concrete and the sleeve. If you put up something with more top load/leverage with a larger mast pipe than a typical 25' vertical, then you just make the hole larger in diameter and a touch deeper. You don't need to use a sacrificial sleeve on the mast; I would just consider the bottom mast set in the concrete sacrificial and simply cut it off at the concrete when you move. Just buy a new mast pipe and consider it part of the cost of moving, or live with it 2' shorter. Or sleeve it if you like when installed.

Like W5HEH suggests, I'd surmise that a hole the size of a 5 gallon bucket (about 1' in diameter") with a 20'- 1" mast in it with that tiny 6M loop in it would stand vertical for many years, if you could get away with it by your landlord.

I won't do anything to his house that would have potential impact. I am using a tripod for a 5BTV and it is working fine with elevated radials. I plan to build the stub tuned radials referenced by butternut manual (I used before with a butternut vertical before I sold it many moons ago).

The bucket is a very good idea but I will probably keep it above ground not buried. I will probably go that route and use a couple Dacron lines tied to fruit trees to keep it from falling over. The M2 loop is extremely light and i think since i will be taking it down after use I am not too concerned about it being a problem staying vertical. It will be a good experiment nevertheless.

Keith

A typical un-guyed 25' vertical, like a Butternut, only needs a post hole dug and a single 80 lb. bag of premix to keep it from listing over time due to its relatively light wind load. I like the single post hole arrangement for such verticals. You can mount a mast/antenna in a sleeve in the hole, fill with concrete and top off the last few inches with soil. Then when you are ready to move, you pull the antenna up out of the sleeve (insure you put anti-seize in the sleeve when it was installed) and cover it with dirt. The only thing lost is the concrete and the sleeve. If you put up something with more top load/leverage with a larger mast pipe than a typical 25' vertical, then you just make the hole larger in diameter and a touch deeper. You don't need to use a sacrificial sleeve on the mast; I would just consider the bottom mast set in the concrete sacrificial and simply cut it off at the concrete when you move. Just buy a new mast pipe and consider it part of the cost of moving, or live with it 2' shorter. Or sleeve it if you like when installed.

The other issue on rental property is that something, other than business fixtures on commercial leasehold property, an item permanently affixed to real property by a tenant becomes, in the absence of an agreement to the contrary may not need to be in writing but as a practical matter has better be, becomes a fixture and the property of the landlord. Courts, due the nature of Ham Radio gear being similar to business fixtures because of licensing, etc,, might have carved out, or might carve out, an exception for Ham Radio gear. But dont count on it unless it has already been done and one has a citation for the case law.

I say this about having something in writing as a practical matter. Most contracts dont need to be in writing. But its harder to prove an oral contract and that difficulty in proving an oral contract grows wth the uniqueness of the subject of the contract. And writing does not be one instrument nor what is traditionally though of a signed writing. A number of writings can prove something and writing includes video and audio tapes, computer memory, and anything which permanently records a thought.

I have been doing that for over 40 years, you rock it side to side
and after you open the sand on both sides about 3 inches each you start
rocking it front to back and when you hear the water making noise you
squat down and give it a tiny tight bear hug and slowly stand up. This
is of coarse in West central Florida in sandy or mucky soil. My XYL
can't even get one started.
My father in law burred several big butted tree bottoms that my XYL had
to have moved, those I had to dig up completely.
(4" at the top and 14" at the bottom)

To get up a 5 gallon pail, dig a post hole next to it, up under the
bottom of the pail a bit and start rocking the post in the concrete,
first one way then the other.
I will admit, both of these take some determination.

I would not attach any thing to the house, with a little wind the home will be damaged. Several years ago I needed a antenna mount and made a removable tilt over, the original build was 30 years ago. Here is a rough sketch,

http://s1102.photobucket.com/user/KD0ZZ/media/Tilt2.jpg.html

I have moved it twice and now is in its final resting place because I plan on passing away on this antenna farm. When you look at the drawing and then click on the right hand arrow you can see it mounted in the ground. This can be covered when you move.

Missed my point , I should have explained better, you use the platform on the ground, the weights are easy to put on and take off, and unless you are killing grass with the platform, there's no potential damage at all. I've had a small hex at 25 feet this way for 4 years, albeit with the rotor at platform level turning the mast. Works well.

Here in Ohio in the hard clay, you'll never rock it to begin with unless the ground has been saturated with water for a couple weeks and even then, it won't rock much. You'll have to dig out one side.

That's good though because foundations don't shift if excavated correctly.

33968. 5 gallon bucket with concrete in ground how to remove

Yahoo group: ham-antennas (2014)
Date: 2014-09-10 20:53:34 UTC
From: james27613@...
Topic: 33968 Message: 33968

hi,

When you fill the bucket with concrete put in an additional 3/4" pipe
that has threads on it, cap it and when the time comes to remove the bucket,
just thread on a 3/4" tee fitting and run a chain in the fitting and use a pipe
or beam as lever to lift up the bucket with the concrete in it out of the ground.

The bucket will have smooth sides that conform to the bucket compared to the
hole in the ground with a fence post and concrete, it will be easy to remove,
just don't try it in the winter.

Yes, but saturate the ground overnight around the bucket to soften the ground and loosen the dirt to bucket surface.

From: Stan Labinsky Jr.
Topic: 33945 Message: 33971

One concern about having the antenna pole exposed at or below grade.

I've seen a commercial tower go over because the concrete block it was set into had a layer of dirt on top of it, contacting the legs of the tower. It was at that point that the galvanizing failed and the steel corroded away.

So, if you go below grade you'll need to add something to protect the below grade tubing.

"And if in a bucket, you can't break it. Why not just leave the concrete and cover it with dirt? It's cheap."
The last line of the original message is easy to accomplish, takes very little work. see below:

I have done this, more or less, by digging a hole, putting a pole in the hole,(makeing sure it was vertical)
and then filling the hole with concrete up to about 8" from the grass level. When finished, it will be sturdy, and
support an antenna, and when you Leave the rental house, dig out the sod and dirt 8" down to the concrete, use a
circular saw with a metal cutting blade to cut off the pole, now it's below ground level, and fill in the dirt and sod.
You'll never know anything was there in a couple weeks, ir you keep it watered so the sod regrows.

About the 5 gallon buried bucket... and its future removal. The buried concrete is a great idea. But it's removal sounds good in theory only. Removing it easily once in the ground? Not so easy. The problem is that a 5 gal bucket of concrete weighs about 300 lb! Good luck pulling that back out of the ground. Ever tried to pull a fence post up out of the ground that is set with just a single 80 lb bag of Quikrete once it has settled for a couple of days? Takes a huge amount of rocking and considerable digging. It's back breaking. Can't imagine trying to pull 300 lb of concrete up without digging around it 180 degrees, breaking it first, tilting it over and pulling it up in pieces. And if in a bucket, you can't break it. Why not just leave the concrete and cover it with dirt? It's cheap.

But just sitting a 5 gallon bucket with 300 lb of concrete in it with such a light load on the ground should work fine, depending on how tall the mast is. But that doesn't get the 6M loop above the eaves.

For perspective on wind loading, a 20' flagpole requires a hole a couple foot across a minimum of 18" deep to keep it from listing over time. But it has a heavy wind load of course if it has a couple flags on it. A typical un-guyed 25' vertical, like a Butternut, only needs a post hole dug and a single 80 lb. bag of premix to keep it from listing over time due to its relatively light wind load. I like the single post hole arrangement for such verticals. You can mount a mast/antenna in a sleeve in the hole, fill with concrete and top off the last few inches with soil. Then when you are ready to move, you pull the antenna up out of the sleeve (insure you put anti-seize in the sleeve when it was installed) and cover it with dirt. The only thing lost is the concrete and the sleeve. If you put up something with more top load/leverage with a larger mast pipe than a typical 25' vertical, then you just make the hole larger in diameter and a touch deeper. You don't need to use a sacrificial sleeve on the mast; I would just consider the bottom mast set in the concrete sacrificial and simply cut it off at the concrete when you move. Just buy a new mast pipe and consider it part of the cost of moving, or live with it 2' shorter. Or sleeve it if you like when installed.

Like W5HEH suggests, I'd surmise that a hole the size of a 5 gallon bucket (about 1' in diameter") with a 20'- 1" mast in it with that tiny 6M loop in it would stand vertical for many years, if you could get away with it by your landlord.

73,

Scott AC8DE

Subject: [ham-antennas] Re: Non permanent antenna U bolt mount

I would mount it on the Ground ,fill a 5gal bucket with quick crete bury it with mounting pipe in it to set your Aluminum masts in , then you can remove it whenever you move easily no attaching to building this should work for a short mast set up like yours . Your landlord would appreciate it as well cause clamps can do some damage and dents. Soil can be just pushed around ! hihi. Enjoy all, 73s, AJ W5HEH

Why just a uarter stick?!?

Use 2 or 3 sticks and you have a nice deep hole for the next antenna project

Oh I get it now. Not on the house but in the backyard. Now that is a cool idea too. I know a ham in San Diego that has one of those and had a five element M2 on it on top of his flat garage.

Thanks,

Keith

>>>> About the 5 gallon buried bucket... and its future removal. The buried concrete is a great idea. But it's removal sounds good in theory only. Removing it easily once in the ground? Not so easy. The problem is that a 5 gal bucket of concrete weighs about 300 lb! Good luck pulling that back out of the ground. Ever tried to pull a fence post up out of the ground that is set with just a single 80 lb bag of Quikrete once it has settled for a couple of days? Takes a huge amount of rocking and considerable digging. It's back breaking. Can't imagine trying to pull 300 lb of concrete up without digging around it 180 degrees, breaking it first, tilting it over and pulling it up in pieces. And if in a bucket, you can't break it. Why not just leave the concrete and cover it with dirt? It's cheap.
>>>>
>>>>

Set your 5gallon bucket in the ground , insert a pvc sleeve that your antenna mast will slide into, add your concrete, .
When its time to move , pull the mast out , dig down to the bucket which you set 12 inches below ground level, and cut the pvc sleeve.
The bucket and concrete are left and buried, it is not worth the effort to remove them , and you still have to find more soil to fill in the hole if you do.
My 2 cents worth

I was trying to check the resonant frequency of my 30 Metre loop antenna (from the Shack end of the coax), what I am not sure about is whether the frequency read out should be at 30 metres or possibly twice that frequency. appreciate some advice on this

Do you want the "technician" or the "extra" [US license classes]
answers? I tend to give the "extra" answer. The "tech" answer is,
"Your analyzer should read an SWR of 2 at the shack end of the coax".
"Tech" answers are short, definite and typically wrong.

Now the "extra" answer: (long, vague and partially right.)

It depends on what you mean by "30 Metre loop antenna". This problem
of naming pervades all kinds of ham antennas.

Is it a "antenna made of 30 meters of wire", or an antenna made for "use
on the 30 meter band"?

Fortunately in the case of loops, a very common kind of loop uses as
much wire as the band name, i.e. a wavelength's length of wire. But there
are other kinds of loops that do not.

Assuming your loop for 30 m uses 30 m of "thin" wire, fed in the middle of
the bottom side of its square shape[*], then the antenna should resonate
at a frequency somewhere in the 30 m band, i.e. around 10 MHz. In fact,
such a 1-lambda loop will resonate at n*10 MHz, i.e. 10, 20, 30,...,
so the answer to your question is "which frequency to read out" is "YES".

[*] notice I had to guess "middle", "bottom" and "square". I also guessed
"vertical plane" for the loop. These are common guesses. Later, I'll
guess RG-58/U for coax type. I'll also guess there is no balun. I also
guessed the height of the loop above ground, but just to irritate the
haters, I won't say what I guessed. Some on this list hate me because
I don't correctly guess their thoughts. Others hate me because I won't
reveal my guesses. I try to please both types.

Now the question becomes, "What will I read?" Well, you should read
an impedance of <mumble> +j0 ohms, i.e. no reactance. That's if you
read the meter at the antenna. At 10MHz, something like 100+j0 ohm.
At 20Mhz, maybe 240+j0, at 30 Mhz, maybe 250+j0, at 40MHz, maybe 300+j0.

At the end of the coax in the shack? Depends on two things, after you
decide on the frequency to read. Let's say you pick 10MHz. Then the
answer depends on the kind of coax and the length of the coax. Picking

the kind of coax fixes two parameters: the characteristic impedance of the coax, often 50 or 72 ohms, and the attenuation factor of the coax, which is to say, how many decibels 100 feet [not meters] of the wire will turn to heat at the chosen frequency. Knowing the input impedance (100+j0 @ 10MHz), the characteristic impedance ("Z0") of the wire, the attenuation constant ("alpha"), the velocity factor ("vf") of the specific coax, and the length of the coax, we can calculate (i.e. predict) what the analyzer will read at the shack end.

For RG-58/U cable, the shack-end impedance can run from 100 to 25 ohms resistive and the reactive part can run from +j35 to -j35 ohms or so. Not all combinations occur. You can read them from a Smith chart, or run a "transmission line" program, such as "TL.EXE". (or ask me nicely...).

Balun? Balun? Did someone say "balun"? No, nobody said "balun".

Dave AB3NR

All antennas operate the most efficiently when they are naturally
resonate at the frequency that you are operating on.
This is most easily determined by sweeping the antenna system with a
return loss bridge. Low reflected power frequently occurs very close to
this frequency, but this relates more to the feedline to antenna match
than anything else.

From: WVØH
Topic: 33978 Message: 33982

This statement is wrong. Resonance has nothing to do with efficiency. Efficiency is all about maximum power transfer from source to load and a conjugate match. For example, (there are many but will expand on one), an extended double Zepp antenna fed with open wire feeders is an antenna that is "non-resonant" but is very efficient by itself. I have an open wire fed 40m doublet that operates as an extended double zepp on 17m. And when I say by itself, I mean that you can introduce inefficiencies with a lossy match from 50-Ω unbalanced to high Z balanced match, and that has to be considered as well.

The definition of resonance is defined as a vector addition of the capacitive reactance and inductive reactance in a complex circuit containing such elements equals zero, leaving a pure resistance in the circuit. Now, this can occur at a 50 Ω point or not. So an antenna that happens to be truly resonant at 50 Ω (which is quite rare) then maximum power transfer can occur.

Now if we consider the addition of a transmission line added to the circuit we can introduce mismatch loss. This loss is the loss due to a complex impedance attached to the output side of a transmission line that is not terminated in its characterisitc impedance. For instance, a 450 Ω ladder line terminated with 50 ohms or vice versa where a 50 Ω line is terminated with 450 Ω. This creates standing waves and subsequently a high SWR on the transmission line.

```
The below phot shows the frequency sweep of an antenna that is resonant at two points. Once
near the center where it crosses the horizontal axis, and again resonant at a place just
past the "5" on the Smith chart". It is resonant at two places.

----------

The next photo shows the same response displayed as an SWR response. Find the two
resonances here. You can't because the response is displaying the magnitude of the response
without regard to phase.

Nice explanation Myron, however the pictures were stripped from the explanation. They need to be added to the photo gallery.

Absolutely correct. Gee...

A resonant antenna is "nice" to have, but that, alone does not effect
efficiency...or at all, for that matter.

Matching impedances for maximum power transfer is the key to
efficiency....like from a final amplifier its the load.

Same deal.

A series trap and a 50 ohm resistor is a perfect match and maximum power transfer, but does not radiate, much. The series trap can be a long wire with X inductance hence reactance and a series cap of opposite reactance. It will radiate some but the bulk of the energy will go to the resistor. I think we are running around the load matrix question without really getting to the core of a efficient radiating antenna.

From: Alan
Topic: 33987 Message: 33987

Thanks very much for all the replies and I very obviously did not be specific enough
about the antenna I am trying to check.
Firstly I have only recently purchased the 259B so have no experience in using it
but going by the instructions resonance should be where it shows minimum reactanceThe antenna is a 10 Mhz loop broadly triangular shaped with the top and feed point up the mast at 30 feet and the bottom of the triangle is about 6 feet off the ground.
Currently it is straight fed with 50 ohm co-ax so I know there is going to be a mismatch.
I don't know the actual length of the co-ax as it comes down from the last to a junction box on the outside of the house then through the brick wallof the house into my shack (about 6 to 7 metres.
The two sloping legs would be approx 12 metres long at the base about 6 metres,
is it likely to be more efficient if I was able to make two of the legs about 9 metres and the other 12 increasing the angle between the two sloping legs??

I will sit down and read through all the replies and thanks a lot for your help

I just took a glance at that. Good call, Mel, that's definitely a
keeper, and kudos to Phil Salas, AD5X, who wrote it. There's more
there than just efficiency, including numerous interesting and sometimes
hard-to-find formulas.

33989. RG 316 experiences/results as feedline ?

Yahoo group: ham-antennas (2014)
Date: 2014-09-13 12:12:49 UTC
From: email4utoo@...
Topic: 33989 Message: 33989

Last time i brought up the topic of a 5 Gal cement bucket as solution, here it got a huge response and we all got something and even some smiles from the answers .
I do not expect the same but still want to know : got some RG 316 on sale recently ,(sorry finished), wanted to see how to use it as a Feedline , yah i know normally not used for this for us Ham Ops. . Have not had a good result so far on transmit for my verticle, (i know i need more Radials), also questioned a pre-molded R8x 100 or so Footer of feedline- so yesterday. Put some PL259s ,(not crimped , hihi one pulled out even after i epoxied it !) i put to much pressure raising it , on my OCF, (off center fed), Dipole up in the Trees . So changed strategy and repaired it and hooked it up to my Vertical , i was trying to contact one of the Route 66 special event stations , and no success, after remembering i did not retune - so after doing it i came back and tried again and the op. told me was much better signal, still not super strong , but never the less could hear me and i was happy with the result .
Sorry long story now my Question -
Tell me chime in , anyone here have tried or have knowledge to share on this or similar Feedlines, i do not have used Lmr 400 or even know what it looks like , or the smaller feedlines. What small lines used for HF with good success, how many Watts did you run ?? Does Crimping have durability ? never tried it . If yes , what brand and best source to save costs . I am not planning to bury it , do not think it was designed for this . We can all learn from my simple Questions , appreciate it .

Just back into this Great hobby in last 6mos , was Ham in 60s as a Teen- i used the Heaviest lines i could afford in those days . 73s, AJ" w5heh - Ozarks

Simple answer = 2.7 dB loss per 100 feet at 10 MHz.
{half of your transmit power lost on 20 meters}

(at 50.0 MHz it's 5.6 dB per 100') {almost 3/4 of your power lost}

Yahoo group: ham-antennas (2014)
Date: 2014-09-13 14:16:46 UTC
From: Don Sanders
Topic: 33989 Message: 33992

Hi AJ, I have not used the RG 316. I have used RG8X for 20 + years up to 600 watts (SB200) with good results. I use 9913 for VHF. I use only solder connectors no crimp and I make sure there is strain/stress relief in each connector. Usually a mil-Dacron line tied both sides and a support point, sometimes with a drain loop to help keep water off the protective covering.

I also have 300 ohm foam/PVC conered feedline to 80/40 all band doublet and 88 foot center fed inverted"L". I use coax to beams, except experimental 17 meter 2 el beam with 17 and 20 reflectors and 15 meter director. Works very well all 3 bands fed with 300 ohm line.

Hope this helps.

Any pvc in the mast structure would break after a while. I think it's safe to assume the default mast is metal.

Before you're inundated with "Don't use grease! It's an insulator!" advice, for two pieces of aluminum clamped together the worlds worst insulator would be grease. The metal comes in direct contact so many places in a greased joint that there will be zero resistance -- at least no more than a dry joint.

The anti-oxidizing hoop made for this purpose is NOT conductive. Take a dab of it and measure across it with a DMM and the reading will be "OL" for open loop.

Capacitance per foot of that small coax is...um..."rather large".

As you, I use it for interconnects on projects, mostly at AF.

Keith - Congrats on that Benin QSO today! I've had my 5BTV for at least 20 years, in several QTH's. The best performance I got out of it was when living in Martinez (next to Walnut Creek / Concord - east bay). I had it mounted on the roof of my one story house, four tuned radials for 40, 20, 15, 10 and two tuned radials on 80. Performance on 10, 15, and 20 was OK, but not as good as my yagi at 40 feet. However, it really shined on 40 and 80 meter CW. I used to work gray line DX in the early morning - tons and tons of Asian stations, including some juicy ones - take a look at my QSL section on my web page: www.w6jhb.com

I now live in Folsom (25 miles east of Sacramento) and have it configured for 40, 30, 20, 15, and 10 meters. It is ground mounted and I've got 40 radials of various lengths buried in the grass. I use it only as a "diversity receive" antenna on my Elecraft K3; the main / transmit antenna is an 88 foot long doublet at 45 feet. The combination of that horizontal antenna and the 5BTV vertical makes QSB a lot easier to deal with.

Anyway, again - congrats and enjoy that vertical!

73, Jim / W6JHB

Ken wrote:

"Capacitance per foot of that small coax is...um..."rather large"."

No different than other coax, even the fat stuff.

Capacitance per foot is IDENTICAL for any 50 ohm coax with the same dielectric constant (propagation velocity); and it doesn't vary very much as the propagation constant changes.

Both the outer and inner conductor diameters scale, so the capacitance stays the same.

RG-316 and the like are very well suited for (a) winding chokes, and (b) going through windows or other tight spaces where the windows have metal and a flat unshielded feedline won't work. At HF. You wouldn't want to run it the whole way to your antenna some distance away, but short runs are OK at HF. But also keep in mind its power handling capability, which depends on the SWR. You can fry your cable.

Regards,
Andy

From: schwartzj22@...
Topic: 34004 Message: 34004

To all,

I have placed a 4nec2 design file entitled, 10-20M BAND VERTICAL.NEC.txt, in the file section. This is not my original design, I just tweaked it. In theory, this is a killer design!

Take a look at it and tell me what you think. I would like to fabricate this in such a way that it is a temporary / portable antenna but I need some tips / help on how best to build this.

One thing to note is the meaning of the word Verttot. For example, Verttot20m = total end height of 20m wire, elevation included.

Any help is appreciated,

Joel – N3GSE

Welcome Dave! As someone said before, just be specific about what youre looking for or just lurk and see what others are talking about.... there is a lot of experience on this board and if you got a question.....just ask.....most know at least something about almost anything. Everybody helps everybody
Cheers,
Dale K8TS

From: osianfion@...
Topic: 34009 Message: 34009

Hi All,
I have an MFJ 4601 window feedthrough panel. It is designed to pass coax, so 50 ohm (nominal) SO-239 connectors. My question to the group is can I use two spare feedthrough center pins to pass 450-ohm ladderline without messing up the match or should I return the 4601 for the mixed connector version? Still unopened in the box but if I can get away with it I would prefer to forgo the hassles of return/exchanging.

Bob,

I would go the next model up, which is the 4602, and spend the extra $10 to get the correct one for the balanced line. That way you do not have to worry about the possibility of any mismatches. Just my opinion.

I agree, although if that was all you had, it would work OK.

Depending on the spacing, there MIGHT be a small "impedance lump" there,
but in most cases, you could probably safely ignore it.

My opinon only.

34014. AW: [ham-antennas] MFJ Window feedthrough question

Yahoo group: ham-antennas (2014)
Date: 2014-09-15 08:44:27 UTC
From: siegfried jackstien
Topic: 34009 Message: 34014

Ignore it ... it will work fine with 2 coax connectors side by side

Or

Make 2 new holes in it and install 2 new feed-trough insulators

.....

The nice thing with using 2 coax connectors for the ladderline is:

With grounding the shields of the 2 connectors you also have a nice
lightning safety arrestor at the shacks entrance ...

BUT depending on antenna and ladderline length used you can have a high
impedance spot exactly at that connector and with a bit higher power have a
flash over possibility there that you would not have with a high voltae
feedtrough without a grounded shield so close

....

To make it short

Use what you have

Test it with grounded and ungrunded shields

And you can change that later if needed

If you have no trouble with flashing overs on any band

Fine ... use the 2 coax connectors grounded and have a bit higher safety

Bob, just for convenience i would use the the model with proper connectors, If you used two center connections and run a short coax inside to them , the impedance should not be affected that much , just be careful to do good quality work . if this was the only one available i would try it out and see , yah returns are a hassle, hihi. I am using my Homebrew Hillbilly Ham Board i made and sprayed it white drilled holes for SO 239s and bolts for mounting a ground , later when i try out some open Feed i will simply drill out to fit the ceramic connectors , when the storms come i unhook everything , will not take a chance , to hard to replace your equipt. and wait etc , hihi. 73s, "AJ" The Hillbilly Ham , Ozarks.

It is.

But the Microsoft Works spreadsheet program is in there too, not part of Microsoft Office but part of Windows.

And many people don't have Microsoft Office. It doesn't come with Windows.

I mentioned OpenOffice and Libre Office, which are completely separate from Microsoft Office and do not come from Microsoft. They are how the rest of us (who don't want to pay Bill Gates for the privilege of using Microsoft Office) get to open .DOC files and .XLS files and .PPT files and ... etc. But alas, it is not fully 110% compatible, there are occasional glitches, and sometimes my fingers default to the Microsoft Office way of doing things.

"Windows 7 here, and it still comes with Microsoft Works in it."

OK. I haven't played with 7 as much as I have with XP, Vista (yes, Vista, and I like it) and 8/8.1. Current computer is a Gateway quad core with 8.1, and no works. Libre Office, along with its estranged sister Apache Open Office are nice for opening almost any file type. Oftimes, MS Office (Word) cannot even open a Works document! Check this out! <http://brunogirin.blogspot.com/2011/04/libreoffice-to-rescue.html>

Um, I would not use grounded coax connectors. A balanced line antenna is not going to be happy and present a good load to a matching network, and will no longer be balanced. Now, if you fed the balanced line through the center conductors of two coax connectors, it might work, but I would just put in a pair of balanced line feeders, and be done with it. Or, just exchange the thing for the next model up and eat the postage.

Are we talking about the same file? That file is named:

"Turning 5BTV Vertical Antenna/Vertical Antenna Initial Set Up.xlr"

Some web browsers do funny things with filename extensions. Maybe yours saw it as an "unknown" file type and changed the file extension to .TXT because it thought it was 'helping' you. Just rename it back to .XLR.

If you were talking about a different file, then this Excel/Works stuff doesn't apply.

Bob wrote:

"can I use two spare feedthrough center pins to pass 450-ohm ladderline without messing up the match"

This is HF, right?

Then the answer is YES -- Absolutely!

You can, it won't mess up the match, and you don't need to change it to the other version. If you want to change it anyway, just to look "prettier", that's fine too; but you wouldn't be doing it to preserve the match. That would be for aesthetic, not electrical, reasons.

At 30 MHz, a wavelength is 10 meters. How long is that "discontinuity" through the SO-239's? Maybe 1/100th of a wavelength? A few thousandths of a wavelength? You won't notice it, and neither will the electrons.

If you were concerned about that minuscule discontinuity, you wouldn't be using ladderline. Ladderline has an impedance discontinuity at every 'rung' or window of the ladder. If it mattered, you wouldn't be using ladderline because all those little discontinuities would mess up the impedance.

Now if you were pushing UHF or a few GHz through the feedthru panel, then it would matter. But not at HF.

Regards,
Andy

"... and will no longer be balanced."

Bob was talking about using a PAIR of coax connectors. Basically, he's got two short barrels which are insulated from chassis, and they handily take banana plugs on both ends. The balance is preserved.

> Thanks for the responses, I will try the grounded solution after checking some numbers.

I've heard of running ladderline to a panel, then turning it into a pair of coax cables, one conductor of the ladder line to each of the center conductors of the coaxes. The shields of the coaxes are connected to each other and grounded. So I have questions:

1) Does it work?
2) Which end should be connected and grounded?
3) SHould the other end leave the shields unconnected/ungrounded?

The goal of this drill is to lead the feed to a balanced tuner, supposing you have one. The shielding is rumored to prevent "RF in the shack". Coaxes should be equal length.

Leaving one end of the shields floating is said to avoid a ground loop.

Comments, anyone? I've never done this, but am curious.

FWIW, I agree with other commenters that using the coax sockets will cause an impedance bump, maybe even some reactance, but nothing you can't tune out later, or may not even notice.

BTW, You can use banana plugs on the ladder line to connect to the coax center conductors. I can also imagine a way to cobble a PL-259 to fit, but I think that might increase the size of the "bump".

You can measure most of this with an antenna analyzer if you've one handy.

You can also place a balun at the window panel and make a transition to coax there. Or put it in a box outside, run a little bit of coax down to the panel. 4:1 balun is traditional for this. The box might also have a switch to short the two sides of the ladder line together and lead them off to ground.

Hi all,
Thanks for the responses. Yes Andy, I am talking about just using the center conductor of two adjacent unused connectors, not splicing into a coax cable. I bought this at my local HRO, or as I call it, "My other paycheck deposit window". They special-ordered it so return would be an extra hassle. The more I think about it, I agree, there should be no appreciable problems, a very small discontinuity at best. Thanks again.

73s,
Bob Cavanaugh - AG6YK

Bob was talking about using a PAIR of coax connectors. Basically, he's got two short barrels which are insulated from chassis, and they handily take banana plugs on both ends. The balance is preserved.

Hi, they do have pgms that will allow you to open office files. I just typed in read xl documents and it displayed several locations to down load the tiny pgm. Used to do this when my office would get a newer version of an office file (we had 2007 and the file was a 2010) and it let us open it without any problems. they have them for docs, and ss.

Have fun

Dr. Don wrote:

"When I downloaded the file it was a.TXT file which is not an EXCEL or WORKS graphic file. It made no sense."

Are we talking about the same file? That file is named:

"Turning 5BTV Vertical Antenna/Vertical Antenna Initial Set Up.xlr"

Some web browsers do funny things with filename extensions. Maybe yours saw it as an "unknown" file type and changed the file extension to .TXT because it thought it was 'helping' you. Just rename it back to .XLR.

If you were talking about a different file, then this Excel/Works stuff doesn't apply.

What is your budget for an antenna? Since you have a nice square roof and if your budget allows for it you could build a four-square antenna vertical array and be able to use it like a vertical 2 element beam.

As for the S-9 type antennas, you can get them fairly cheap right now on Cheap ham while they last and the 31 footer is a good choice. If you attach a wire at the top and run it out at least 6o feet or more you have an inverted L which works nicely on 80 and if you have a good tuner can be made to work on 160 too.

How about trying a design I came up with many years ago:

Take 4 metal masts at least 20 feet high and insulate them from the bottom, Next attach a loop so it make good mechanical and electrical contact with the four masts. Next, feed either one of the masts at the bottom or directly the loop like you would only attach the feed line at one corner and pick the corner that the opposite direction would give you the greatest coverage away from it. Use a 4:1 or at least a 1:1 current balun if using coax, or better still directly fed with 450 or 600 OHM feed line to a tuner and it covers 80-10 and if the total including the masts are at least a 1/4 wave on 160 it will tune there as well.

I have used this at many locations and built dozens for others. It works great on DX as you get several take off angles depending on fee point and it works both Vertically AND Horizontally due to the masts and loop being polarized as they are.

I call it the Bob Tail Curtain Loop. 450 or 600 OHM line is best to use as feed line but you can go through a good balun (current not voltage) and use coax if you prefer. Depending on your rig, I have used 50-75 coax including RG-6 (Cable TV coax) with excellent results. I prefer 450 or 600 OHM as it transfers the most RF into the antenna as opposed to unbalanced coax.

Since you have four corners I would think about seriously, low wind load, just make sure the mast are guyed and you have a solid insulator on each mast if concerned about wind. This has stayed up in 80 MPH wind sustained for over an hour. It worked on mountain tops in high winds, easy to put up or take down. Handles whatever power your feed line, (balun) and tuner is rated for and is very low noise on receive. On transmit due to the size of the loop it might be multiple wavelengths on the higher bands 20-6. which computes to some gain as well.

This antenna is very easy to build, doesn't cost much depending on what you use to construct it, EMT, Pipe, Masting and wire. Feedline you can make yourself out of 14-10 guage insulated or open wire and osme plastic coat hangers, or other type of non conductive spreaders, wind a balun if needed and either trim it to resonance or better still get a good tuner with a built in balun.

Good luck

Hi Ed.

I composed the spread sheet on Microsoft Word Spread Sheet. It has an XLR extension. Read about XLR files here... http://pcsupport.about.com/od/fileextensions/f/xlrfile.htm

There should be free read only XLR programs that you can download available on the Internet.

Yes Dave you can do that, I've seen where whole 'balanced' shielded runs were implemented in that fashion.

However, and this could be a big stopper, there will be added capacitance between the two legs of the balanced line caused by the presence of the common tied shields and the cable's center insulator.

Will this be a problem? Definitely... maybe! It will all depend on what the impedance looks like at the tuner, with and without that extra capacitance.

If the antenna is already in place and the feeder is already coming in to the shack, adding the intended coax and feed through connectors and testing for the ability to match the antenna on all intended bands will show you whether the gate is open or closed to the idea.

Stan

> Thanks for the responses, I will try the grounded solution after checking some numbers.

I've heard of running ladderline to a panel, then turning it into a pair of coax cables, one conductor of the ladder line to each of the center conductors of the coaxes. The shields of the coaxes are connected to each other and grounded. So I have questions:

1) Does it work?
2) Which end should be connected and grounded?
3) SHould the other end leave the shields unconnected/ungrounded?

The goal of this drill is to lead the feed to a balanced tuner, supposing you have one. The shielding is rumored to prevent "RF in the shack". Coaxes should be equal length.

Leaving one end of the shields floating is said to avoid a ground loop.

Comments, anyone? I've never done this, but am curious.

FWIW, I agree with other commenters that using the coax sockets will cause an impedance bump, maybe even some reactance, but nothing you can't tune out later, or may not even notice.

BTW, You can use banana plugs on the ladder line to connect to the coax center conductors. I can also imagine a way to cobble a PL-259 to fit,

but I think that might increase the size of the "bump".

You can measure most of this with an antenna analyzer if you've one handy.

You can also place a balun at the window panel and make a transition to coax there. Or put it in a box outside, run a little bit of coax down to the panel. 4:1 balun is traditional for this. The box might also have a switch to short the two sides of the ladder line together and lead them off to ground.

For little cost you could make an Inverted L. Just use the dimensions for the W3DZZ, which will make the total length about 54 feet. You can always put an 80 metre trap in and then it will cover 160 as well. Of course it would then be a bit longer.
I have made one to cover 160 as well and it really flies on all bands.
Good luck and good building

to each other and grounded. So I have questions:

1) Does it work?
2) Which end should be connected and grounded?
3) SHould the other end leave the shields unconnected/ungrounded?"

Yes it works.

What to do with the shields is an interesting question. The thing to keep track of, is where the currents flow.

In coax, the current through the center wire is exactly mirrored by the current in the shield around it. That happens whether you want it to, or not. At the ends of that coax, where does that shield current go? There should be a path.

Let's make an assumption that the signal on the balanced line is balanced.

In the case of the pair of coax cables, the other coax has the exact opposite currents flowing. Thus, you can tie the two shields together (of the two lengths of coax), and do that on both ends. That completes the circuit for the shield currents. There is no need to also ground them, but I suppose you could. There should be zero current into that connection to ground (to the extent that the signal current on your balanced line is balanced).

If you don't give a path for the shield current to take, e.g., if you cut the shield off at one or both ends of the coax, it forces a common-mode current on the coax. You will get a current on the outside of the coax that pretty much matches the current in the center wire. That's probably not good. So in response to this:

"Leaving one end of the shields floating is said to avoid a ground loop."

I would say that is NOT the right thing to do. In effect, you now have two fat wires (as fat as your coax) being your parallel line. If you run those coax lengths through a metal panel, or near and around stuff that you thought you were protecting by using coax, you would in fact be making it worse instead of better.

Ground need not enter into this picture at all, I think. There is no NEED to ground the coax shields, as long as you provide the necessary paths for

currents to take, as described above.

But if you did ground them, the presence of "ground loops" might not matter. I say *might* not because they are, after all, loops, and loops can induce currents from nearby RF fields, and you are near a radio antenna, so there may be some localized pickup into them. So maybe the better thing to do is to (A) connect together the shields of the coax pairs, on both ends, and then (B) tie one of the ends to ground, if you like.

Regards,
Andy

A G5RV is designed without a balun. Why do people keep asking about one? The guy that invented it designed it without any balun. The short piece of balanced line going into the coax (called a "stub") makes an impedance match, thus stopping the coax loss from a high swr. With a balun, you get a balanced wire antenna. No longer a g5rv. With a long run of coax you get coax losses. Better to bring the balanced line, any length, into or near the shack to a balun there. I use a MFJ-1777 with a tuner. Works great. Balun is in the transmatch. No coax needed.

Use standoffs. Can even be made of pvc pipe.

A G5RV is a good multi band antenna. Not sure you will get 6 meters on it though. The last comment is exact and precise. No balun on a G5RV. The ladder line does the matching, in a sense. I have been running G5RVs for many years and they work very good with a tuner. You will need a manual tuner usually for this antenna as most auto tuners in rigs won't be able to match the impedance. Running the ladder line all the way to a tuner with a 4:1 balun in it or putting one just before the tuner is another great antenna, (doublet).
You can pull the ladder line down at a slight angle and use a wooded steak to tether the ladder line off to keep it away from the pole. Bungee cords work great for this.
Good luck

1/4" PVC is going to be very flexible. I have used bamboo fishing poles in the past for an experimental antenna. These are the long, one piece bamboo poles that were used many years ago with only a piece of line and a hook on it, no reel. I found them at a fishing/bait shop locally and was surprised that people still use these for fishing. Anyway, they were relatively cheap and held up to the weather quite nicely. My experimental antenna was up for longer than I had planned and it survived well.

The 20 meter wire is about 12.5 feet from center post to the arm attachment.
There fore I would believe the 15 meter would take about 9 feet to the
attachment.
If you do not bend arms, not needed for monoband, a 10 foot support would
be good.

Here's a couple of websites that ought to help:

http://www.hex-beam.com/
in particular, monobeam hexbeams are given at
http://www.hex-beam.com/specs

This site is cyclopedic:
http://www.karinya.net/g3txq/hexbeam/

Here are some limits. The six spreaders will be below the wires by a distance H. The hexagon will have a circumfrence of C. You decide an H and C.

The minimum length of a spreader will then be sqrt((C/6)*(C/6) + H*H), i.e. the hypoteneuse of the triangle with sides C/6 and H. There is no maximum length except your capacity for the absurd. An estimate for a *practical* maximum is C/6+H, which is still long. Too long is good, that is why you were issued a hacksaw.

Basically, you decide how much tension you want in the wires, and that decides how long the spreaders and the ratio H/C should be. It's easy enough to conduct actual experiments with a length of the candidate pipe, from the /specs URL (above) I'm guessing that 5 feet of PVC for a 15m hexbeam might supply a trial size. Clamp one end to the work bench, then put a wire or nylon cord on the free end, and pull. If you put a fish scale in the cord, you can even measure the tension. (Or use dead weight, a bucket, and a pulley in the obvious way.)

You can see when and where the PVC will break, too. "Sound engineering" would say that 1/4 the breaking tension is max working load. Assuming PVC doesn't take a set in the hot sun, or become brittle in the frozen depths of winter.

When making a set of spreaders and their hub, attention to detail, making the effective length of each spreader the same, and attaching things at exact "hex" points will make for a planar result.

For reference, the tension in a (steel) guitar string is around 17 pounds, or for the Imperially challenged, 75.6 newtons. :-) (I'll be merciful this once: 7.7 Kgf).

Subject: [ham-antennas] 40M Rotary Dipole with Mosley TA-40-KR Add-On Kit

How hard is it to make a rotary dipole using the Mosley TA-40-KR kit? Got the traps and would like a to make a monobander instead of the having the additional band in the TA-33-M yagi. Guess that by building it as a rotary dipole, it should have more bandwidth versus being installed to the TA-33. Comments, ideas? Also, want to install in another place plus want to have 40M via another feedline to the shack.

Anyone.

34051. Inconsistent 5BTV resonance

Yahoo group: ham-antennas (2014)
Date: 2014-09-17 13:22:40 UTC
From: Keith Heimbold
Topic: 34051 Message: 34051

I have been taking down my 5BTV after every use as it is elevated mounted portable on a tripod. I have been having to retune nearly every time I pull it upright as the match on all bands moves up by several hundred kHz. It is a necessary part of renting this house that I don't leave it erect for neighbor issues plus I have a two year old son that could hurt himself on it when I am at work. Not sure if I should take the entire antenna apart to see if there is something wrong with it or I should just get used to retuning it as part of the situation I am in.

I was also curious if anyone has tried putting a coil at the feedpoint to lower 40m resonance. I cannot get it to resonate elevated even with perfectly cut resonant radials. Best I can get is about 4:1. I was thinking about my old butternut and how there was a coil for 80m across the feedpoint. I was curious if something like that would work for the 5BTV on 40m.

Hi Keih.

DX Engineering sells a matching coil for vertical antennae that is suppose to help obtain a lower SWR on 40 & 80 meters without effecting the SWR of the higher frequencies. You can read more about the coil here. http://www.dxengineering.com/search/department/antennas/product-line/dx-engineering-vertical-antenna-matching-networks?autoview=SKU&N=4294953330&sortby=Default&sortorder=Ascending
When I was having trouble obtaining a low SWR on my Hustler 5BTV antenna, I contacted DX engineering and they suggested adding more radials before installing a matching coil. I followed their suggestion and it worked for me.

I posted a spread sheet on this forum outlining the effect adding radials to a 5BTV had on a Hustler 5-BTV. .

If you have trouble finding or opening the work sheet. contact me at worahm@... and I will send you the file. You will need MS Word or Works to open the file.

On your space , why not try a Fan Dipole ? I also would highly recommend books like Les Moxon's,-- HF Antennas for all locations---", used on line , i just got a good one . Also look up the files section here , and spend some time on eham's forums has articles as well . Experimentation will give you success in your specific location - consider some exotic antennas as well like 2 phased verticles, Sterba Curtain, and even a Vertically mounted By Square or Loop , enjoy the journey , by the way i saw a decent vertical , by DX on QTH.com was very low cost . 73s, AJ W5HEH

Keith,

The fact the tune moves up every time you set it up is quite curious. A BTV is usually quite stable. It's never a bad idea to disassemble an antenna and see if something is wrong, if you have the time. But I'd make that a last resort.

How do you know your radials are "perfectly cut"? You can't do it by measuring a length, especially when installed close to the ground. The only way to tell if they are resonant where you want them to be is with an antenna analyzer, much like a dipole. Since you are close to the ground, that throws any theoretical physical measurements off. If you get within 1/4 wavelength of the ground, the tune change is significant. A 40M radial just a few feet off the ground is going to be way off in tune from the theoretical measurement and is going to have low Q since ground capacitance is a big deal. It may not even be possible to get the 40M radials tuned when really close to the ground because it will act like it is on the ground due to ground capacitance.

Another question is how far is the feed point of your antenna from the radial field? Frankly, you'd do better to put the BTV right at the ground so the feed point is close to the ground and lay out 8-16 radials about 30 feet long when you are going to use it. This is a much easier and more predictable way to get consistent results. Tuning should calm down this way as well.

As far as a shunt coil goes, indeed, it is a good idea to have one. However, it only has a slight affect on 40M but has a more pronounced effect on 80M. Don't waste the money on a $70 shunt coil from DX. They make good products, but you can wind one yourself on an approximate 2" OD piece of PVC from any solid insulated wire (suggest 12 gauge for mechanical stability) with about 12 turns and then use a combination of removing turns and stretching the coil to get your lowest 80M dip as low as possible, which will help 40M a bit. Once you get it where you want, you just tape it down so it doesn't move. But don't expect miracles. You've got to get 40M to behave a bit better than 4:1 before you add the shunt coil. I suspect the radial situation is the problem.

Do you have a common mode choke at the rig? You need one with a vertical in most cases. You can easily get inconsistent SWR readings due to common mode problems that are prevalent with verticals, especially when close in to one.

Question - Why did you trade down from a Butternut to a BTV? A BTV is a fine antenna, but much more lossy than a Butternut, but the Butternut can be more of a challenge to tune and the coils easily damaged in a "portable" situation like you describe.

Scott,

Thanks for all your thoughtful suggestions. I am going to try a different location and height for the antenna and retune. It is unfortunate that it has to be taken down after very use. It is truly like being portable.

I got rid of the butternut when I put up my SteppiR three element a few years back at my old QTH and I wish I had it back now but I think you are right that it would do far worse with the coils and the constant up and down than the hustler. The butternut was also in this kind of elevated setup and it to gave me tuning fits. I must have taken it apart five times in a couple years, replacing the 15m wire, door knob caps etc. but regardless of the difficultly with the nut it did perform great with the stub tuned radials (which I still plan to build). Thanks for the reminder.

Scott,

A few thoughts. The first is that it might be far easier to live with being off a few hundred kHz at the feed point and then just compensate for it with an antenna tuner at your rig. For the short run of coax you must have, your losses resulting from higher feed-point SWR into a 50ohm transmission line would be negligible. Your rig's S-meter won't even notice it. If it can't, you can't. Of course, you could use a remote tuner at the antenna, but that's yet more more expense and setup time.

My other thought is that as long as you must get the antenna out of sight (during daylight hours?) after each on-air session, perhaps you can use a tip-over mount such as what DX Enginering sells (~$70) so you can just lay it down instead of taking it apart. Of course the feasibility of that depends on the size of your yard, the hazard for kids, etc. Those issues aside, it sure makes the back-and-forth of antenna adjustment a lot easier.

HI Keith.

Is there any way that you could camouflage the 5-BTV as a flag pole, bird feeder or perhaps place antenna close to the trunk of a tree?

Some folks, who live in restricted communities down here in Florida slip the antenna inside PVC or fiberglass tubing and hang a flag or bird house on top.

Check here for more ideas. http://www.g4ilo.com/stealth.html

Bill

Oh. Sorry. I just see so many people asking if they need to put a balun on the G5RV at the balanced line and it makes me say "uhhh?" (Like Scooby Do.) Yeah, the G5RV needs no balun, and the 102 foot legs would likely tune it to 160 meters, and require a longer stub. Wouldn't it?

Now, the article on Wikipedia calls for a balun, but that would make the feedline no longer a part of the antenna, would just make it a balanced line dipole, and you would be tuning SWR on the coax. I am sure you know what I am talking about but can't verbalize.

Myself, I would use balanced feeder into the shack (Varney even said it was the best idea), and use a balun right at the matcher, or use a balanced line matcher. You can see the two antennas on MFJ. First the G5RV <http://www.mfjenterprises.com/Product.php?productid=MFJ-1778> and then the 1777 <http://www.mfjenterprises.com/Product.php?productid=MFJ-1777>. They are the same length. I just think the doublet has a chance of working better. I use mine every day, and have worked as far off as New Zealand. Wish Africa would start coming in...

I use the MFJ 1777 with the feedpoint at at 30 or so feet, and about 35 or so feet of feedline into the shack into a Heathkit SA-2040 (THAT is another story, and it really works), and barefoot, it works great. When I cut in the Heathkit SB-200 (yet another story), cracking a pileup sometimes is just too easy...

73 OM es Good Luck!

I am falling victim to a ruthless Homeowners association and their Draconian rules. As with many fellow Hams, its the antenna that causes the problem and not the Ham Station itself. There are a few ways to build a remote station using RemoteShack, RemoteRig, etc., but looking through all these remote rig devices I had a "what if" moment. What if instead of having a remote station with your rig located in some distant QTH, what if you sat in front of your rig and just YOUR antenna was located at some distant location. This way you have full and up close control of your rig, at the designated QTH listed with the FCC, and your signal is sent via ??????? to a remote receiver and then up and out your own personal antenna? I'm sure that this has been addresses before but with Microwave and all of the other new technologies that seem to be developed every day it seems that maybe someone a lot smarter than me has a solution. Located about 1/2 mile away from me I have access to a 250 ft structure where I can place an antenna but in my neighborhood I cant even place a vertical on the ground. If I could get me signal from my QTH, to the 250 foot structure then I would be in HAM Heaven. Is there anyone doing this? I am sure that there are people who live in a valley and want to locate their antenna on top of the mountain while keeping their station at home. How do those hams do this?

Any ideas or suggestions?

34062. Hustler 5BTV 80m 40m resonance problems with add on coil

Yahoo group: ham-antennas (2014)
Date: 2014-09-19 17:34:31 UTC
From: Jimmie K9JFK
Topic: 34062 Message: 34062

Hi,

I want to add a short "be wary of" when it comes to adding a loading coil to overcome 40 and 80m swr problems on a Hustler 5BTV. However, I "think" it only applies when your installation is "good" and "in decent ground". My 5BTV was ground mounted in "good to very good" soil over a radial field of 36 x 66ft radials.

Tuning was normal on all bands except for 40 and 80 meters. Adjusting for one caused the other to change dramatically; a number of different coil configurations were tried. Only one band could be fixed; if 80m swr came down, then the 40m swr went up, and visa versa. I thought I'd need to tap the coil and use relays to achieve operation on both bands. However, I went "back to basics" and decided to tune the antenna like a "homebrew".

The antenna's spokes and capacity hat blades were removed. After that, I started to lengthen the 40m section; the SWR started to come down. Eventually, I found that the SWR was good when the section was lengthened just under 34 inches. The 80M section then tuned up per the installation instructionswithout effecting 40M operation.

I've given the "Cliff Notes" version of the installation problems; the process took a couple of weeks and three or four antenna "tear downs" searching for "hidden" problems.

Yes, my antenna is taller than "spec" by a little less than a yard. No more tuning problems have been encountered, not even when the 12 and 17m bands were added. It also loads up without protest on 60m with a little help from a tuner.

Maybe the ultimate solution for the 40/80m problem is not coil?

Here is the ARRL link. BTW: My congressperson responded in a couple of days to a letter reminding him that we hams play an important role in emergency communications. Here in earthquake/wildfire country, that happens a lot more often than you might imagine. People, this is serious business. Most hams I know are not thinking (maybe dreaming) about pouring a new 8' square concrete pad and mounting a 100' tower. I would be ecstatic if I knew I could mount a 2m/70cm Jpole and two HF mag loops on my roof without consequences. Let your representatives know that this is an important issue.

All I can think of are the RF losses for that distance! The other methods you mentioned are probably better choices, if there is infrastructure there @ tower for your rig. If not, I feel your pain. I got lucky where we bought. Restrictions, yes, but the tower problem is (so far) concerning wind generators on towers as far as the County is concerned. In my HOA, we have restrictions, but over the years everyone living here has created their own transgressions, so a suit would be all encompassing! No one want to get rid of their out of restriction stuff!

Loss is a problem. At 10 MHz that would be ~3 dB or half your power with 7/8" Heliax and VERY costly.
I have a remote antenna system 850 feet away using 7/8" air Heliax but limit the operation to 40 meters, 0.76dB loss. Acceptable.

Randy,
Since the HOA is going to complains about an external antenna for a point-to-point microwave link, I would start with the Fidelity Communications (the cable company) and see if they provide a Ethernet Private Line (EPL) over DOCSIS product and connect to the tower site via IP.

Potential Issues:

- Finding room at the site for your equipment, and securing it

- Adding IP controls to your rigs

- Cost of routers and network kit.

- Recurring costs for the cable modems at both locations.

The most obvious answer is a very long feedline. Aside from all the power loss, that also requires right-of-way access to run the feedline the whole way. If you can do that, and can afford that much super-low-loss feedline, great.

When that's not possible, the usual answer is to put the transceiver at the remote location and operate it remotely. Then the only "interconnects" you need are audio in, audio out, and remote control of the rig. But you say you want the transceiver with you, and that poses problems.

The (more or less) three functions that the transceiver needs to provide, are (1) a modulator, (2) a power amplifier, and (3) a receiver. One could, I suppose, put the modulator in your home where it still has the look-and-feel of being a transceiver at your fingertips, and the power amplifier and receiver at the remote location. Then you could use radio (i.e., microwaves) to beam the modulator's output to the remote amplifier, and have a return path for the receiver's audio. I think no matter how you carve it up, it would be a heck of a lot easier to just put an entire transceiver at the remote location and remotely control it.

Microwaves can send a low-level signal from point A to point B, but not the high-power output of a ham transceiver.

Also, beaming the receive RF back over microwaves, without first processing it at the antenna end, is not likely to work well unless you almost duplicate the whole receiver there.

We also don't know what ham frequencies you had in mind. Since you talked about a 250 foot structure, did you want to put a 2m or 440 antenna on top of it, or a big HF beam?

Regards,
Andy

Read obout Remote Rig. And the Kenwood TS-480.

All you need is a basic int3rnet connection at the tower site and your control point.

I do this less the remote rig costs personally and work HF and 6 when traveling the US from my iPad and even at times from my Android.

Good luck.

Remember that 3dB, or "half your power" is less than a half an S unit, and is not noticeable in a QSO. If you take a sound generator and make a sound with it, then turn it up by 3dB, most people cannot tell. So, if you are going to do something that loses you 3dB, you need to work out if it is going to benefit you enough to make up for the loss, or if the loss is not enough to worry about. 6dB is where you begin to hear something, and can be about 1 S unit. This is why a lot of hams buy a 6 or so dB amp, like a 600 watt amp. It is not really enough down from a 1500 watt amp (4 or so dB) and is a LOT less expensive. I use a Heathkit SB-102, and when trying to crack a DX pileup, I notice that when I kick it in (around 5 to 6 hundred watts), suddenly I am heard. Only paid $250 for it (seller said "lights up"), and took the chance and flipped the switch. Whole lot cheaper than a 1500 watt, and no one can really tell after the signal has gone a few thousand miles.

So, do what you need to do, and realize that 3dB is not going to hurt that much. When you start losing 4 or more, then it is time to call Houston...

I think you mean an SB-200. I have two of those (and an SB-102 and a
HW-101), one of the SB-200s which I bought for $50 and which had been
abused by a CBer. He had gotten the finals so hot that they scorched the
plate coil. It works just fine now.

>, and when trying to crack a DX pileup, I notice that when I kick
> it in (around 5 to 6 hundred watts), suddenly I am heard.

Yes. I get about 600 watts out of mine when I use it conservatively. No need
to drive it to max. Power input to my SB-200s is about 50 watts for full
output. I cleaned up some of the circuitry and the amps are more efficient
now. One big difference was to double the value of the filament choke...

> Only paid $250 for it
> (seller said "lights up"), and took the chance and flipped the switch.

I paid $300 for my first one: it was owned by a blind ham who didn't know
that one tube was not lighting due to a bad socket. She couldn't see it
(obviously) and her husband is not a ham and never noticed.

I use it every day for traffic handling. It is very reliable.

I am also modifying each of them, one at a time, for full-QSK using Rich
Measures' method. That method REALLY works.

> Whole lot
> cheaper than a 1500 watt, and no one can really tell after the signal has gone a
> few thousand miles.

In my experience, the only very noticable thing that a full 1500 watts does is reduce the effects of QSB a whole lot. Signal strength on the other end doesn't appear to be much different, but it DOES reduce QSB effects.

> So, do what you need to do, and realize that 3dB is not going to hurt that much.
> When you start losing 4 or more, then it is time to call Houston...

Personally, I'd wait until I find a 6dB difference... ;-)

And even then I think I would work on the antenna system before the amplifier.

Thanks Ken. I did say SB-102, didn't I? I had one back in the 1980's, and it worked like a champ. Yes, mine is a SB-200. And, yes, you are right, you probably don't need to call Houston until you are losing more than 6 dB. And, yes, the antenna is the first place to look.

Since this is antennas, I am running a 102 foot doublet into a balanced wire tuner, a Heath SA-2040. I have always had good fortune with a balanced wire antenna, and rarely use anything else.

Hello !
Any use the SOLARCON A-99 ON 10/12/15/17 and 20 m. band ? any modifications ?

How it work ?
Thanks for helping .....!!!

I can't speak for All Solorcon' A99's - because I only have experience with mine.
You will need some type of antenna tuner, either internally or externally to the transmitter.
You will need to get it at least 50' above good ground.
You will need to deploy at least 12 radials 1/4 wavelength long, for the longest length - you wish to operate on.
I have radials cut for 10, 15, 17 meters.
You can tune it by shortening it a couple of inches off the top, or by removing the top section and replacing it with the whip from a quarter wave mobile - stainless steel 104 inch whip.
Then cut the whip to resonance on 10 meters. Mine is cut for 28.400 MHz...

You ought to be able to get a match of at least 10:1 or better on all these bands.
10. 12, 15, 17 meters.

Hello all,

I don't know whether it is allowed in this group what I'm doing now.

I have only started my ham activities recently with a Patcomm PC-500 dual band QRP transceiver. I have the band modules for 80 and 20 meters, but I would like to have modules for the other ham bands as well.

If, perhaps, you have one lying around, that you don't use any longer, please contact me off list (PA4Q@...).

34083. Problem with 160-m inverted V fed with ladder line

Yahoo group: ham-antennas (2014)
Date: 2014-09-23 20:36:24 UTC
From: wa1rkt@...
Topic: 34083 Message: 34083

I'm wondering if I've been doing it wrong all these years.

Right after the terrorist attack on the WTC on 9/11, after being QRT for many years, I put up an inverted V cut roughly for 160 meters, fed with ladder line, thru a 1:1 current balun down near the shack window, to a succession of tuners at one time or another (currently an LDG AT-1000Pro) to the rig, currently an IC-746Pro and AL-811H amp running about 700 watts.

I didn't pay too much attention to the leg lengths since the plan was to use it on 160, 80, 40, and 30 meters, plus several CAP and MARS frequencies some of which are fairly far from the nearest ham band, so it really wasn't practical to try to cut it for resonance on any one band, hence the need for the ladder line, balun, and tuner.

The antenna has worked well all these years but there are some frequencies where I think it really should work but it doesn't, not very well, meaning the tuner can't find a match in a few places where calculations show it should. Recently I borrowed an MFJ 269 antenna analyzer and did a check for resonance points and found them far removed from where I figured they should be. So I took down the antenna, cut the legs more carefully, and put it back up with coax feed in place of the ladder line, and trimmed it for 1.9 MHz where I got an SWR of 1.2 to 1. Great for 160, of course not so great for any other ham bands I'm interested in (80 and 40) or the CAP/MARS frequencies in that range... I got it to work on all those frequencies but I'm sure I was getting plenty of loss in the coax in most cases.

Once I got it cut for the middle of 160, I put the ladder line and balun back on and now it's not resonant at anywhere near where it should be.

I've always assumed that if you cut an antenna for a half wavelength at some frequency and then feed it with ladder line and a balun (keeping well in mind the need to stay away from certain critical ladder line lengths), you should get resonance points at the fundamental and at each harmonic (not just the odd harmonics). At even harmonics the impedance will be through the roof but the imaginary ("j") component of the impedance should theoretically be zero and in practice should be at a low point, isn't that true? In other words, regardless what the feedpoint impedance is... low at odd harmonics, high at even... it should be resistive at the fundamental and each harmonic.

That certainly isn't what I'm seeing here... with ladder line, the resistive impedance point (the point of lowest imaginary impedance component) is below the lower limit of the MFJ-269, then again at around 3.1 MHz where I get approx. 25+/-j10 ohms (the MFJ-269 will not tell you the direction of the imaginary component). The next resonance point is at 8.22 MHz where I get approx. 52+/-j23 ohms. At the design frequency of 1.9 MHz I get approx. 14+/-j349 ohms.

This is with a feedline of 78 feet which according to my calculations (which could be wrong) should be well within a "green zone" of acceptability for any frequency up through 30 meters or so. I also tried it with a feedline of 68 feet and it didn't make a significant difference.

Clearly the resonance points with coax feed and with ladder line feed are far, far apart from each other, not at all what I expected. So how do I figure the resonance point at 1.9 MHz using the ladder line?

Rick,

I am far, far from being an expert, but in my case I have an 88-foot long doublet fed with ladder line. I use a 4:1 balun at the shack end and run the antenna into either an Elecraft KAT500 tuner, or the built-in tuners in Elecraft K3 and KX3. I use this antenna setup on 40 through six meters. As I was told when I put it up and now feel comfortable with - don't worry about it being resonant. The ladder line provides a very low-loss path for your RF to the antenna and the tuner takes care of the mis-match. It works. The tuners are happy with it on all the bands. Once installed, I marched through each band, letting the tuner(s) find a match every 30 - 50 KHz or so and store them in memory. Haven't looked back since.

You "may" want to try a 4:1 balun, just to see if it make a difference. My guess is that it'll correct the trouble spot(s) you are seeing, but might move them somewhere else.

Just my 2 centavos worth. YMMV.

Jim / W6JHB

I have heard that if you are using a tuner, esp. on a multiband antenna, you DON'T tune the antenna for resonance. You should trim the antenna a bit short or long to give the tuner something to tune against. This was, at least, for the SGC line of tuners so YYMV (plus, how reliable is all of the info you read on the interwebz anyway?).

Good afternoon, Geoff.

Point is, the antenna fed with ladder line is far, far away from resonance at the design frequency of 1.9 MHz. So, no problem giving the tuner something to tune against :-). Antenna tuners are amazing beasts, especially the current crop of autotuners from folks like LDG. But they're typically only specified for an SWR of 10:1 or so. I've been operating mine with SWRs far in excess of that and they seem to work fine most of the time. But to give you just one example, my 160-meter inverted V with 1.2:1 at 1.9 MHz when fed with coax, exhibits such a high SWR when fed with ladder line that my autotuner really struggles trying to find a match and in some cases fails. The MFJ 269 shows an SWR of greater than 31:1 at that frequency. Asking an autotuner to handle that is asking too much I think.

No one has asked yet, but yes, I have (1) tried a different balun... no change; and (2) removed and re-installed all connections at each end of the ladder line and at the connect points for each antenna leg with new terminals, no change.

Rick WA1RKT

Good afternoon, Jim.

I've heard the same... don't worry about resonance... that's why when I first put up this antenna I didn't worry too much about leg lengths. I use this on a good-sized list of CAP and MARS frequencies, some fairly far from any ham band, so it's a lost cause trying for resonance anyway. But one of my big problems... with this supposed 160-meter antenna... is that the tuner struggles mightily trying to find a match on 160 meters, and in many cases fails completely. That's when I decided to start off with something that's resonant on 160 and let the other bands fall where they may... and that's when I discovered that what I thought was resonant, isn't. So I'm trying to find out if my whole concept of resonant antennas fed with ladder line has been wrong all these years... seems like it has, in which case, how do you determine the correct length for resonance with a ladder-line-fed antenna?

As for the 4:1 balun, I have tried that and as you say, it just moves the problem areas to somewhere else. A switchable 4:1/1:1 current mode balun would be great if it were not for the fact that the balun is only accessible by going outside and climbing a ladder.

I could try switching a 4:1 unun in and out here in the shack, but that still begs the basic questions about resonance and ladder lines.

Hello Rick,

A lot of good input, however, the point is that a resonant inverted V puts a terrible load on the tuner for all bands unless you give it a little help.

While I have several inverted V antennas and modeled them successfully, none of them liked the even harmonics. So, I switched to the same length antenna but fed it OCF. It requires a 4:1 balun and a 1:1 current choke but gives very reasonable performance and the tuner doesn't have to work so hard. Example: I have a inverted V antenna where the apex is at 120 feet and is pretty much a equilateral triangle for 160 meters. OK but I feed it at the middle of one side. OCF. Works well on the bottom three, 160, 80, & 40 with a tuner of course, but coax fed no ladder line.

On the other hand if you have the room, as I do, I put up quadrature double extended zepps on 160, yep 351 feet long fed in the middle with about 150 feet of 600 ohm ladder line off my 180 foot tower. Works ALL bands with a tuner.

Just some thoughts.

Mel, K6KBE

34090. Motor-home Antenna

We are full time Rv'ers living in our motorhome. Motorhome has an aluminum roof and the sidewalls are aluminum as well.. Endcaps front and rear are fiberglass. Own a Ameritron SDA-100 screwdriver antenna.

Currently I have set up on a tripod 20 feet in front of RV about 10 foot in the air. Have it guyed down and have it grounded via a stake driven in the ground. Have not tried transmitting yet as I am a new ham and stil ltrying to get the feel for everything.

Would you see any merit to mounting on the trailer hitch on the rear of the motorhome. Could pretty well leave intact all the time, with the exception of removing the whip before moving. Coils would just extend a couple of inches above the rear endcap. Thanks for your suggestions
Gregg KK4WJG

>> of them liked the even harmonics.

Good evening, Mel.

Understood. The impedance on even harmonics will be sky-high, that's well known. But my point is that it should be resistive or nearly so. Fed with ladder line, mine is not, not even close, not on the fundamental and not on the even (or odd) harmonics, the impedance is highly reactive. That's what I'm trying to understand.

>> So, I switched to the same length antenna but fed
>> it OCF. It requires a 4:1 balun and a 1:1 current
>> choke but gives very reasonable performance and
>> the tuner doesn't have to work so hard.

That is my Plan B. If I can't get this inverted V to work with ladder line I plan to extend one leg, shorten the other leg, install a 4:1 current balun and feed it with coax. I have another OCF dipole for 80 meters and it works quite well.

>> On the other hand if you have the room, as I do...

Yes, well, there is that :-). I actually have a fair amount of room, considerably more than the average ham I think, but still there are limits. This afternoon I measured my yard for space to add 60 feet to one leg of my inverted V to make an OCF for 160 while leaving the feedpoint where it is (there are reasons why it's vastly preferable to leave the feedpoint where it is rather than feed partway down one leg as you have done). It just barely fits... but it does fit.

I don't get to put up 180-foot towers.

>> Works well on the bottom three, 160, 80, & 40
>> with a tuner of course, but coax fed no ladder line.

My feedline length is about 75 feet. I'm trying to avoid the high loss that a high SWR on a coax line will exhibit. Keep in mind that I need to be able to use this thing on a list of CAP and MARS frequencies, some of which are a fair distance from any ham band.

Gregg, while using the hitch would be convenient, I've read several articles by some of the well experienced folks on one of the other forums which say that it's not the best option. As the base of the antenna is placed closer to the earth on the vehicle, the efficiency of the antenna goes down, by quite a bit.
Your ten foot mount while not as convenient will give you a better system. To make it even less convenient, quarter wave vertical antennas (like your screwdriver) really do like to have a decent radial field beneath them... it's like the other half of the antenna.
Mobile HF antennas depend on the capacitance between the vehicle chassis and the earth to operate (for the return currents). This path is very lossy and wastes lots of your power, but for a movable vehicle it's the best you can have. I'm thinking a car or pick-up truck, here.
I've seen various articles talking about roll-out, roll-up radial systems. You might want to look for them as well.
Another thing comes to mind, the distance from a tongue mounted antenna to anyone in the vehicle through the fiberglass wall. Unless you're running low power, you might be hitting yourself or your other with a bunch of RF, perhaps more than is OK for you.

Things to consider,

Stan

We are full time Rv'ers living in our motorhome. Motorhome has an aluminum roof and the sidewalls are aluminum as well.. Endcaps front and rear are fiberglass. Own a Ameritron SDA-100 screwdriver antenna.

Currently I have set up on a tripod 20 feet in front of RV about 10 foot in the air. Have it guyed down and have it grounded via a stake driven in the ground. Have not tried transmitting yet as I am a new ham and stil ltrying to get the feel for everything.

Would you see any merit to mounting on the trailer hitch on the rear of the motorhome. Could pretty well leave intact all the time, with the exception of removing the whip before moving. Coils would just extend a couple of inches above the rear endcap. Thanks for your suggestions

Have you tried adding 1/8nwave more ladder line, or removing same.
Often this will change the impedance enough to allow tuner to make a match.

I guess I would lay out a counterpoise for 160, tie the twin lead together and feed it as a long wire. Not neat but have done this with 80 meter doublet. I have not operated 160 for over 10 years.

34102. Re: [ham-antennas] Motor-home Antenna

Yahoo group: ham-antennas (2014)
Date: 2014-09-24 03:33:16 UTC
From: Stan Labinsky Jr.
Topic: 34090 Message: 34102

First, the antenna will most likely be grounded to the car through the coax shield and the radio's negative lead. Still, I'd bond the shield to the vehicle's chassis near the radio, keeps the power wiring from trying to play antenna.
But you will need to make sure that there's a fuse in the radio's negative lead besides the usual one in the positive. Right, I said the negative. Reason is, and it is a stretch but like any warning it's there 'cause some guy got bit by it. 'Seems that the car's negative lead from the battery to the starter in this story failed and when he cranked the engine, the radio's wiring tried to pass the starter's couple hundred amps of current... smoke, lots of smoke. This assumes that the radio will be tied directly to the battery which is typically recommended by the manufacturers.
I'd do a search of this forum and other antenna related forums for radials. You should get lottttts of hits. Typically radials are cut for the particular band of interest at a quarter wave length each. Cut them for the lowest band you expect to work. Then, if you had them on spools you could roll them out to the required length, a thin tent peg could hold them in place. Three or four would do the trick. Could even have them marked for each of the bands you work so you'd only have to measure them out once. Wouldn't need to be very heavy, eighteen or twenty gauge would be plenty and still have some reasonable strength without being too stiff to work with. Since they will be laying on the ground, the length shouldn't all that critical.

Now I'm taking the understanding that you were intending to operate non-mobile. Radials dragging down the road might upset a few folks, the cops most likely.

Morning. I had a similar tuning issue, several years ago, and it came down to a questionable quality balun. The 4 to 1 current balun, in a sealed PVC tube from a supposedly reputable manufacturer, turned out to be nothing more than enameled motor rewind wire, about 22 AVG, on a core no bigger than a quarter. It had fused and shorted. It was rated at 300 watts, but I doubt it would have worked at 20 watts. My rule now , is to never buy anything I cannot open up and look inside. There is a tremendous amount of garbage out there. One 4 to 1 current balun a local ham bought, turned out to be nothing more than a 6 inch galvanized nail, with abt 10 turns of cheapo RG 58 coiled around. Not a balun at all, but a gypo RF choke and not even a good one at that. He paid 50 bucks for it online, and it came in a sealed PVC tube.

I use a number of baluns, and they have all come from Balun Designs in Texas. There are other manufacturers out there, but I happen to have come across these guys first, and am very happy. If you have a mind for it, email Bob at Balun Designs, explain your problem, and and antenna in detail, and I am sure he will come back with a recommendation for you. The product is top grade, rated in the 3 to 5 KW range, and could easily handle the current and voltages on your 160 mtr antenna.. You may also want to build your own open wire feedline, as opposed to twinlead. A lot of the twin lead out there is of questionable quality too!

73 John and good luck

Also, take a carbon composition 200 ohm resistor and put it on the high side and check it out with the analyzer. I do that at swap meets and you would be surprised at how many I pass over as junk.....

If you are gonna park and operate it is worth looking at portable Moxon beams and Hex Beams both can mount on your short mast , if you have trees you can use, i would throw up long wire antenna with a tuner , on my place i used a 1 oz weight with 30lb fishline casted way over the trees then tie a light rope to raise your wire , if you are using very light wire then tie your wire direct to the line . sometimes it is better to ask for Forgiveness, shoot them up safely and quietly , hihi. Enjoy the Journey, 73s, AJ W5HEH

ps my antenna is a OCF dipole feed is rg8x, 4:1 balun, my Tuner is inside my Rig but i also have a portable tuner i built , Emtech,Zm2 and a QRO type full legal limit ol' Heathkit 2060A , have you checked out the RV service net on 40 meters, they will have some experiences to share .

> Once I got it cut for the middle of 160, I put the ladder line and balun back on and now it's not resonant at anywhere near where it should be.

OK.

>
> I've always assumed that if you cut an antenna for a half wavelength at some frequency and then feed it with ladder line and a balun (keeping well in mind the need to stay away from certain critical ladder line lengths), you should get resonance points at the fundamental and at each harmonic (not just the odd harmonics). At even harmonics the impedance will be through the roof but the imaginary ("j") component of the impedance should theoretically be zero and in practice should be at a low point, isn't that true? In other words, regardless what the feedpoint impedance is... low at odd harmonics, high at even... it should be resistive at the fundamental and each harmonic.

"cut an antenna": to adjust an antenna, feedline, baluns and other hardware
until an "SWR" meter looks "good". This, I gather, is what hams usually
mean.

"Resonant": means that an item in question has no reactive impedance.
Antennas, when resonant, have an impedance, which we call ZL ("Load impedance")
of R+j0. For a dipole in free space, R is about 72 ohms.

MEASURED AT THE FEED POINT. Keep that in mind.

I simulated a 160m dipole, 15m high, inverted-V, over real ground, and it
"resonated" at 1.84MHz, with a calculated feed-point impedance of
ZL = 34 +j0 ohms. This is not surprising. The 50-ohm VSWR is therefore
about 1.4, also unsurprising.

Your statement about even and odd harmonics is correct.

> That certainly isn't what I'm seeing here... with ladder line, the resistive impedance point (the point of lowest imaginary impedance component) is below the lower limit of the MFJ-269, then again at around 3.1 MHz where I get approx. 25+/-j10 ohms (the MFJ-269 will not tell you the direction of the imaginary component). The next resonance point is at 8.22 MHz where I get approx. 52+/-j23 ohms. At the design frequency of 1.9 MHz I get approx. 14+/-j349 ohms.

MEASURED AT THE FEED POINT. But you're not keeping that in mind.

You're not measuring at the feedpoint, you're measuring at the end of
an unspecified length of ladder line. (Presumably nominal 450 ohm --
actually 400 ohm).

At the feedpoint, the 3MHz resonance should be about 7500 ohms.
But you measure 25 +/- j10.

>
> This is with a feedline of 78 feet which according to my calculations (which could be wrong) should be well within a "green zone" of acceptability for any frequency up through 30 meters or so. I also tried it with a feedline of 68 feet and it didn't make a significant difference.

78 feet is 23.77 meters. 1/4 wavelength is 40 m. 24/160= .15 (~1/6) wave.
Trust me, it is easier in meters. Ten feet, or 3 m is, at 160m,
about 3/160 or about 1/50 of a wave. As the Germans say, "macht es nichts".

Be careful about phrases like "any frequency".

> Clearly the resonance points with coax feed and with ladder line feed are far, far apart from each other, not at all what I expected. So how do I figure the resonance point at 1.9 MHz using the ladder line?

Well, one reason they're far apart is that coax has a so-called
velocity factor ("vf") of about 0.66 for solid polyethylene dielectric.
Ladder line's vf is about 1.0. (Often taken as .95).

Supposing the antenna to have no reactance at its feedpoint, then we
expect the feedline to have no reactance at n*vf/4 wavelengths distance,
where n = 1,2,3,4....

For vf=1, that would be at 1/4, 2/4, 3/4, 4/4,.... wavelengths or at
40, 80, 120, 160,... meters from the antenna. These will alternate,
such that 40, 120, ... will transform high antenna resistance to low
resistance, the others, 80, 160,... ("half-wave multiples"), will not
transform the antenna's resistance at all.

For coax, the places 40, 80, 120, 160m turn into 26.4, 52.8, 79 and
106 meters. (approximately).

To calculate more specifically, use the program "trline.exe", which
ARRL once supplied to those buying the "Antenna Book". There are also
transmission line calculators at various places around the web.

I have no idea how MFJ measures SWR for ladder line. I cannot advise
how to hook up ladder line to a SO-239 plug, other than to guess there
ought to be a 1:1 balun involved, wound from a transmission line with
an impedance of sqrt(50*400) = 141 ohms, good luck finding some of that.
(You can make it, see books by Sevick (not Cebik).)

Sorry for not providing any recommendations about using a vertical Zepp
or butterfly-mango array suspended from a captive balloon.

If you are talking about radials that are going to be draped on the ground or just small fractions of a wavelength from the ground, don't bother to cut for resonance, as they will not be resonant as the ground itself comes into play. Rather, just make them at least 20 percent longer than your antenna is tall. It's really that simple. It's a long study if you want to go into it.

There is a lot to read on this subject, but I would suggest N6LF's research to be the definitive information you would want to look at on verticals and radial systems.

http://www.antennasbyn6lf.com/design_of_radial_ground_systems/

Subject: Re: [ham-antennas] Motor-home Antenna

First, the antenna will most likely be grounded to the car through the coax shield and the radio's negative lead. Still, I'd bond the shield to the vehicle's chassis near the radio, keeps the power wiring from trying to play antenna.
But you will need to make sure that there's a fuse in the radio's negative lead besides the usual one in the positive. Right, I said the negative. Reason is, and it is a stretch but like any warning it's there 'cause some guy got bit by it. 'Seems that the car's negative lead from the battery to the starter in this story failed and when he cranked the engine, the radio's wiring tried to pass the starter's couple hundred amps of current... smoke, lots of smoke. This assumes that the radio will be tied directly to the battery which is typically recommended by the manufacturers.
I'd do a search of this forum and other antenna related forums for radials. You should get lottttts of hits. Typically radials are cut for the particular band of interest at a quarter wave length each. Cut them for the lowest band you expect to work. Then, if you had them on spools you could roll them out to the required length, a thin tent peg could hold them in place. Three or four would do the trick. Could even have them marked for each of the bands you work so you'd only have to measure them out once. Wouldn't need to be very heavy, eighteen or twenty gauge would be plenty and still have some reasonable strength without being too stiff to work with. Since they will be laying on the ground, the length shouldn't all that critical.

Now I'm taking the understanding that you were intending to operate non-mobile. Radials dragging down the road might upset a few folks, the cops most likely.

Subject: Re: [ham-antennas] Motor-home Antenna

Gregg, while using the hitch would be convenient, I've read several articles by some of the well experienced folks on one of the other forums which say that it's not the best option. As the base of the antenna is placed closer to the earth on the vehicle, the efficiency of the antenna goes down, by quite a bit.
Your ten foot mount while not as convenient will give you a better system. To make it even less convenient, quarter wave vertical antennas (like your screwdriver) really do like to have a decent radial field beneath them... it's like the other half of the antenna.
Mobile HF antennas depend on the capacitance between the vehicle chassis and the earth to operate (for the return currents). This path is very lossy and wastes lots of your power, but for a movable vehicle it's the best you can have. I'm thinking a car or pick-up truck, here.
I've seen various articles talking about roll-out, roll-up radial systems. You might want to look for them as well.
Another thing comes to mind, the distance from a tongue mounted antenna to anyone in the vehicle through the fiberglass wall. Unless you're running low power, you might be hitting yourself or your other with a bunch of RF, perhaps more than is OK for you.

Things to consider,

Stan

Subject: [ham-antennas] Motor-home Antenna

We are full time Rv'ers living in our motorhome. Motorhome has an aluminum roof and the sidewalls are aluminum as well.. Endcaps front and rear are fiberglass. Own a Ameritron SDA-100 screwdriver antenna.

Currently I have set up on a tripod 20 feet in front of RV about 10 foot in the air. Have it guyed down and have it grounded via a stake driven in the ground. Have not tried transmitting yet as I am a new ham and stil ltrying to get the feel for everything.

Would you see any merit to mounting on the trailer hitch on the rear of the motorhome. Could pretty well leave intact all the time, with the exception of removing the whip before moving. Coils would just extend a couple of inches above the rear endcap. Thanks for your suggestions

/*snip*/
Just a stupid question from an outsider.
Was the antenna cut from the normal formula (that allows for the "end effect", not a physical quarter wavelength) and are real good quality end insulators being used? (not just rope)

From: siegfried jackstien
Topic: 34083 Message: 34112

What i would do is

Antenna halfwave for 160

Ladderline halfwave for 80!! (or better say quarterwave for 160!)

And then a high ratio balun down to 50 ohms

On 160 halfwave dipole and low to ground has low impedance ... that is transformed up with the quarterwave transformer (ladderline) ... and then back down with the balun

On 80 your dipole has high impedance

Ladderline is halfwave (no transforming) and so also high impedance on balun (and back down to 50 ohms)

On 40 and higher the same thing ... mid to high impedance on both ends of ladderline ... and a low impedance after the balun to coax (not exactly 50 ohms but in the range of any tuner)

That is nearly same setup that I use here (except that I use a fullsize deltaloop for 160) ...

....

Greetz

I like options. Here is a nice simple multi-configuration antenna. for 80-10+ meters, cut the antenna for OCF 45 and 90 feet. In restricted spaces, configure the antenna as a end fed 90 foot with a 1:1 choke balun after the tuner. Use the antenna turner to resonant. Where space allows, configure as a OCF antenna with the 4:1 balun and a 1:1 choke balun and antenna tuner. Should be the best of both worlds.
Mel, K6KBE

From: Gary H. Harmon, Jr.
Topic: 34114 Message: 34114

According to QRZ, The fellow handling the sale of this stuff is in WI and shipping is not an option. He told me "local sales only." But he has a ton of stuff including lots of Heathkit items.

Contact Dennis Lerum. His email address is

k9nam1@...

If you plan to go, he lists Heathkit HA-10 amplifier parts. I need a meter. If he has an extra meter and it can be bought reasonably and you can mail it to me, please let me know.

Reminder, email Dennis, NOT me.

From: siegfried jackstien
Topic: 34090 Message: 34115

With some antenna tools like 1:1, a 1:4 (both BALUNS not UNUNS!!) ...

And maybe a 1:9 unun

An outotuner or manual tuner

And a spool of wire

Some coax ... and a fishing pole

And an ANTENNA LAUNCHER

All that in a small toolbox

And you can erect any antenna anywhere

I take with me all thins that I could probably need (when oin on filedday as an example) ... see what my local options are ... and then build a proper setup

Sure some pre-cut wires may help for faster building such things

But even without that it is not that difficult to build an antenna in any location

Especially if you work against your motor home it is very easy ...

But sure with 2 trees (or one tree and a fishing pole fixed to the motor home) you also could build up any setup (ocf or ladderline fed doublet)

That motorhome setup is nearly the same thin as you would go on fieldday

So ... antenna building is not that magic ... just take the riht parts with you and you will be "on air" in minutes ... in any location

Dg9bfc

Sigi

Ps I just built an antenna launcher from a garden sprayer ... works superb ... and cause the pump is built in you do not need to take any other thins with you (compressor or bicycle pump or ...)

34117. ANTENNA LAUNCHER FROM GARDEN SPRAYER

Yahoo group: ham-antennas (2014)
Date: 2014-09-25 17:45:44 UTC
From: siegfried.jackstien@...
Topic: 34117 Message: 34117

I found a neat way how to build a compressed air launcher (tennisballs and some fishing line ... you sure know how to use that)

the tricky thing is that i used a garden sprayer as the tank

see pictures (cause a picture tells more then a thousand words hi hi)

https://groups.yahoo.com/neo/groups/ham-antennas/photos/albums/1300298411
https://groups.yahoo.com/neo/groups/ham-antennas/photos/albums/1300298411

the neat thing is the few needed parts and the VERY short way for the airflow

and the sprayer came with pressure gauge, safety valve ... and the handgrip had the trier valve included ... how neat is that?!?

so needed things

2x 75mm coupler (one cutted and filed down to match the modded sprinkler valve)

a garden sprayer

1 inch sprinkler valve

some glue (I used 2k epoxy cause there are 3 different plastc materials to be glued together and a solvent glue would maybe not work)

the pictures sure tell how it is built but if you have questions feel free to ask

Yes ... but a special way how it is built

Modding the valve and mounting the coupler direct to the case of the valve

Is it transformed to a high impedance by 1/4 wave of line?
Apparently so. 1/4 wave transforms a "low" impedance at the antenna
to a "high" impedance at the end of the transmission line, and also
transforms a "high" impedance at the antenna to a "low" impedance at
the end of the line. "High" and "low" seem to mean "relative to the
characteristic impedance of the line. (In this case 400 ohms).

If we take the ZLoad of the antenna as 34+j0, then 1/4 wave of 400 line
transforms it to 4700 ohms, according to an as-yet-untrusted program
I have here.

The same line would transform 5000 ohms at the Load to 32+j0 at the end
of line, according to the same untrusted program.

> On 80 your dipole has high impedance
> Ladderline is halfwave (no transforming) and so also high impedance on balun
> (and back down to 50 ohms)
>

According to a NEC2 sim, about 7500 ohms. This would be untransformed
by a 1/2 wave of 400 line. This is going to need some fairly hefty
additional matching, right? Such as a 150:1 transformer? This transformer
would be a disaster on 160m, of course, so should be switched out.

This is a tuning situation akin to matching an end-fed 1/2 wave wire.
Well, that's what the antenna is on 80m -- two 1/2 wave end-feds.

On a loop, though, you don't alternate high-low-high-low, do you? At least you don't for a square loop fed in the middle of the bottom. Zload will be something like 100,230,210,... for 160m, 80m, 40m...

That will transform by 40m of 400 line to 1600, 230, 210. Yeah, some sort of usual balun (4:1, I imagine) would make that all tunable easily (400, 57, 52 ohms). 20m should be "easy", too, for the loop.

Excellent, Siegfried.

At what pressure do you operate the gun? Are the photos of two different constructions?

Tom

No tom

All Pictures where made before glue added (except picture "finished")

Finished picture is with a second coupler in line glued to the tank (so barrel is not wobbling)

First cut down the sprinkler valve ... (see pictures)

Outer diameter matches inner of the coupler ... so with some cutting on the coupler I could glue that modded sprinkler valve direct to the one coupler

And then coupler and valve glued to the tank

Second coupler is just for mechanical strength (to hold the barrel)

Barrel is a thick walled 75mm pipe (inner matches tennisballs with a not too tight fit)

For a "soft shot" only 10 psi needed

With 20 psi you can reach all higher trees here in northern dl

With 30 psi you can overshoot SEVERAL high trees

Just tested once with 50 psi .... and I thought ... wow ... that will fly to the ISS ... grin (over 50m high and about 150m away it came down)

So ... depending on height needed the used pressure is around 15-20 psi only

You can use more if needed :-) just do some more pumps

The trigger valve from the sprayer is glued in the top of the sprinkler valve

Thats it ... nothing special except the cutting and filing work on the coupler and the sprinkler valve ... yes that takes some time ... but that construction makes a compact design and the air has only one 90 degree turn in the valve

In other constructions you have 2 curves in the valve ... plus one or 2 elbows and some adaptors ... that all lowers the impulse to the ball

With my compact design you have high performance even with only low pressure used

....

Any questions about construction??? Feel free to ask

Dg9bfc

Sigi

Ps playing with the dog makes a lot of fun ... grin

Did you see the pictures in my album

That shows clearly how all comes together

Modding of the sprinkler valve:

Cut down at the bottom (exhaust side) ... round the edges in the centre bore

Ream or file out the entrance side of the valve helps to lift up performance

(the threads are not needed cause you glue in the outer side of the flange)

Cut down and file down the 75mm coupler till it matches the valve (see again the pictures)

Demount the electric magnet in the sprinkler valve (if mounted) and close its hole with some 2k epoxy

In centre of the top of the sprinkler valve is a screw (for manual open of the valve) ... demount that screw and glue in the trigger valve in that hole

That□s is the special work that has to be done:

Modding the sprinkler valve for pneumatic action (see above)

Modding the sprinkler valve that it can be glued direct in the 75mm coupler and in the tank (cut in parallel to its bottom and so cut away the exhaust flange)

Cutting down and filing down the coupler

.....

Glue all together and let it sit over night

Stick in the barrel and have fun :-)

To: ham-antennas@yahoogroups.com
Subject: RE: [ham-antennas] Motor-home Antenna

If you are talking about radials that are going to be draped on the ground or just small fractions of a wavelength from the ground, don't bother to cut for resonance, as they will not be resonant as the ground itself comes into play. Rather, just make them at least 20 percent longer than your antenna is tall. It's really that simple. It's a long study if you want to go into it. There is a lot to read on this subject, but I would suggest N6LF's research to be the definitive information you would want to look at on verticals and radial systems. http://www.antennasbyn6lf.com/design_of_radial_ground_systems/ 73, Scott AC8DE From: ham-antennas@yahoogroups.com [mailto:ham-antennas@yahoogroups.com] Sent: Tuesday, September 23, 2014 11:33 PM To: ham-antennas@yahoogroups.com Subject: Re: [ham-antennas] Motor-home Antenna First, the antenna will most likely be grounded to the car through the coax shield and the radio's negative lead. Still, I'd bond the shield to the vehicle's chassis near the radio, keeps the power wiring from trying to play antenna. But you will need to make sure that there's a fuse in the radio's negative lead besides the usual one in the positive. Right, I said the negative. Reason is, and it is a stretch but like any warning it's there 'cause some guy got bit by it. 'Seems that the car's negative lead from the battery to the starter in this story failed and when he cranked the engine, the radio's wiring tried to pass the starter's couple hundred amps of current... smoke, lots of smoke. This assumes that the radio will be tied directly to the battery which is typically recommended by the manufacturers. I'd do a search of this forum and other antenna related forums for radials. You should get lotttts of hits. Typically radials are cut for the particular band of interest at a quarter wave length each. Cut them for the lowest band you expect to work. Then, if you had them on spools you could roll them out to the required length, a thin tent peg could hold them in place. Three or four would do the trick. Could even have them marked for each of the bands you work so you'd only have to measure them out once. Wouldn't need to be very heavy, eighteen or twenty gauge would be plenty and still have some reasonable strength without being too stiff to work with. Since they will be laying on the ground, the length shouldn't all that critical. Now I'm taking the understanding that you were intending to operate non-mobile. Radials dragging down the road might upset a few folks, the cops most likely. 73, Stan From: mailto:ham-antennas@yahoogroups.com Sent: Tuesday, September 23, 2014 10:16 PM To: mailto:ham-antennas@yahoogroups.com Subject: Re: [ham-antennas] Motor-home Antenna Stan do appreciate the advice. Any suggestions for radials.. Wire on the ground. Length etc. Could ground the system to my car with a little rearranging. Sent on a Sprint Samsung Galaxy Note® 3 -------- Original message -------- From: "'Stan Labinsky Jr.' k2stn@frontier.com [ham-antennas]" Date:09/23/2014 9:03 PM (GMT-06:00) To: ham-antennas@yahoogroups.com Subject: Re: [ham-antennas] Motor-home Antenna Gregg, while using the hitch would be

convenient, I've read several articles by some of the well experienced folks on one of the other forums which say that it's not the best option. As the base of the antenna is placed closer to the earth on the vehicle, the efficiency of the antenna goes down, by quite a bit. Your ten foot mount while not as convenient will give you a better system. To make it even less convenient, quarter wave vertical antennas (like your screwdriver) really do like to have a decent radial field beneath them... it's like the other half of the antenna. Mobile HF antennas depend on the capacitance between the vehicle chassis and the earth to operate (for the return currents). This path is very lossy and wastes lots of your power, but for a movable vehicle it's the best you can have. I'm thinking a car or pick-up truck, here. I've seen various articles talking about roll-out, roll-up radial systems. You might want to look for them as well. Another thing comes to mind, the distance from a tongue mounted antenna to anyone in the vehicle through the fiberglass wall. Unless you're running low power, you might be hitting yourself or your other with a bunch of RF, perhaps more than is OK for you. Things to consider, Stan From: mailto:ham-antennas@yahoogroups.com Sent: Tuesday, September 23, 2014 6:38 PM To: ham-antennas@yahoogroups.com Subject: [ham-antennas] Motor-home Antenna We are full time Rv'ers living in our motorhome. Motorhome has an aluminum roof and the sidewalls are aluminum as well.. Endcaps front and rear are fiberglass. Own a Ameritron SDA-100 screwdriver antenna. Currently I have set up on a tripod 20 feet in front of RV about 10 foot in the air. Have it guyed down and have it grounded via a stake driven in the ground. Have not tried transmitting yet as I am a new ham and stil ltrying to get the feel for everything. Would you see any merit to mounting on the trailer hitch on the rear of the motorhome. Could pretty well leave intact all the time, with the exception of removing the whip before moving. Coils would just extend a couple of inches above the rear endcap. Thanks for your suggestions Gregg KK4WJG [Non-text portions of this message have been removed]

Hello Scott, we got off track about the Screwdriver antenna. Sorry, I have also used my HI-Q mobile screwdriver antenna with a lot of extra wire added to the end of the whip. While it won't let you operate 10 or 6 meters easily, it does a great job of increasing the eff of the radiated signal on the lower bands including 160. Requires the use of a antenna analyzer to make tune up simple, but it does add a lot to the signal strength. Just a thought from us random camper/RV types, hi.

This assumes that the radio will be tied directly to the battery which is typically recommended by the manufacturers.
I'd do a search of this forum and other antenna related forums for radials. You should get lottttts of hits. Typically radials are cut for the particular band of interest at a quarter wave length each. Cut them for the lowest band you expect to work. Then, if you had them on spools you could roll them out to the required length, a thin tent peg could hold them in place. Three or four would do the trick. Could even have them marked for each of

the bands you work so you'd only have to measure them out once. Wouldn't need to be very heavy, eighteen or twenty gauge would be plenty and still have some reasonable strength without being too stiff to work with. Since they will be laying on the ground, the length shouldn't all that critical.

Now I'm taking the understanding that you were intending to operate non-mobile. Radials dragging down the road might upset a few folks, the cops most likely.

73, Stan

Subject: Re: [ham-antennas] Motor-home Antenna

Gregg, while using the hitch would be convenient, I've read several articles by some of the well experienced folks on one of the other forums which say that it's not the best option. As the base of the antenna is placed closer to the earth on the vehicle, the efficiency of the antenna goes down, by quite a bit.
Your ten foot mount while not as convenient will give you a better system. To make it even less convenient, quarter wave vertical antennas (like your screwdriver) really do like to have a decent radial field beneath them... it's like the other half of the antenna.
Mobile HF antennas depend on the capacitance between the vehicle chassis and the earth to operate (for the return currents). This path is very lossy and wastes lots of your power, but for a movable vehicle it's the best you can have. I'm thinking a car or pick-up truck, here.
I've seen various articles talking about roll-out, roll-up radial systems. You might want to look for them as well.
Another thing comes to mind, the distance from a tongue mounted antenna to anyone in the vehicle through the fiberglass wall. Unless you're running low power, you might be hitting yourself or your other with a bunch of RF, perhaps more than is OK for you.

Things to consider,

Stan

Subject: [ham-antennas] Motor-home Antenna

We are full time Rv'ers living in our motorhome. Motorhome has an aluminum roof and the sidewalls are aluminum as well.. Endcaps front and rear are fiberglass. Own a Ameritron

SDA-100 screwdriver antenna.

Currently I have set up on a tripod 20 feet in front of RV about 10 foot in the air. Have it guyed down and have it grounded via a stake driven in the ground. Have not tried transmitting yet as I am a new ham and stil ltrying to get the feel for everything.

Would you see any merit to mounting on the trailer hitch on the rear of the motorhome. Could pretty well leave intact all the time, with the exception of removing the whip before moving. Coils would just extend a couple of inches above the rear endcap. Thanks for your suggestions

Don’t get rid of the screwdriver yet. In the long run you will be happy you have it.

As you stated you are a new ham and have to learn what to really do to enjoy the hobby. I suggest if you add some radials to your setup you can have some decent results.

If you also look at adding capacity hats to your mast length you can significantly improve your lower band performance.

Anyway do not make any quick decisions at this point in time as it will most likely just cost you money.

You just got you license and all that means you now have the license to learn and have fun. Take you time stay on this list and read and study. I could give you lots of ideas on what you could do but they would be based on my thoughts and how I operate. However, if you start slow and steady it will be lots of fun, then as you learn about antennas and improve your system you will hear more and make more contacts.

I also suggest you try and participate on the 3905CC club nets and start to make some contacts and get some QSL cards. I also suggest you join ARRL and also participate with LOTW (Logbook of the World).

There is so much to the hobby as you will soon learn.

Cheers
Don

If you are talking about radials that are going to be draped on the ground or just small fractions of a wavelength from the ground, don't bother to cut for resonance, as they will not be resonant as the ground itself comes into play. Rather, just make them at least 20 percent longer than your antenna is tall. It's really that simple. It's a long study if you want to go into it.

There is a lot to read on this subject, but I would suggest N6LF's research to be the definitive information you would want to look at on verticals and radial systems.

Subject: Re: [ham-antennas] Motor-home Antenna

First, the antenna will most likely be grounded to the car through the coax shield and the radio's negative lead. Still, I'd bond the shield to the vehicle's chassis near the radio, keeps the power wiring from trying to play antenna.
But you will need to make sure that there's a fuse in the radio's negative lead besides the usual one in the positive. Right, I said the negative. Reason is, and it is a stretch but like any warning it's there 'cause some guy got bit by it. 'Seems that the car's negative lead from the battery to the starter in this story failed and when he cranked the engine, the radio's wiring tried to pass the starter's couple hundred amps of current... smoke, lots of smoke. This assumes that the radio will be tied directly to the battery which is typically recommended by the manufacturers.

34132. Trap dipole?

Yahoo group: ham-antennas (2014)
Date: 2014-09-26 07:44:48 UTC
From: ikkefestbrems1@...
Topic: 34132 Message: 34132

I'm planning to make a trap dipole.
My question is in what band edge and how far from the edge do i place the cut-off frequency.

In my case in region 1 80M (3,500-3,800Mhz), what frequency do i select?

34133. Re: [ham-antennas] Trap dipole?

The most success I've had building/tuning traps is when I've measured the resonant frequency of the trap while directly attached to an analyzer through a 50:200 Ω balun connected across the 200 Ω output. I tune the trap for a zero crossing of X on the R,X graph, and that's it. All other methods of loose coupling and VSWR have produced resonant frequencies that are way off. If you think about it, loosely coupling the trap by means of a few wire wraps close to the coil is in no way a representation of the actual circuit in use. Probably a great way to obtain the unloaded response but it's attached to wire, the antenna wire, and there is a certain amount of loading there and loose coupling doesn't get you to where you want to be.

34134. Antenna question

Yahoo group: ham-antennas (2014)
Date: 2014-09-26 22:28:49 UTC
From: Alex Netherton
Topic: 34134 Message: 34134

Hi folks;
I am a 35+ year licensed Ham, and have used almost all kinds of antennas, from re-purposed CB antennas to store bought beams to balanced wire antennas through a tuner, and the last is what I want to ask about.
I was in a meeting the other night and a fellow was talking to a MARS group on an undisclosed frequency (near 40 meters) on a G5RV Jr. He was getting good signal reports, and then went to get onto a ARRL net on 75 meters. He had a little trouble tuning, and low battery, and thus was unable to do so, but some of the things he was saying threw me a little.

He told us that when he was operating on the MARS frequency that the tuner and mismatch of the line ate up most of his signal, thus his output on 40 meters with a G5RV Jr. (cut for 40 meters, at around 60 feet or so) from a 100 watt output from his rig, was reduced to about 5 watts radiated power at the antenna. This flies in the face of everything I have learned about matchers, antenna efficiency, and radiated power. I know that coil losses, say for a 10 foot screwdriver on 75 meters is just about that, but a G5RV? Was Lewis Varney's effort in vain? He opined that the only antenna that could really radiate was a resonant one. I am sure that is mostly true, but if that is the fact, why do so many have such good results with balanced wire and tuners?

I run a doublet, which is sort of a G5RV with balanced wire right into the shack. It is 102 feet long, and I tune it with a Heathkit SA-2040 through an internal balun. I often chase DX, and have cracked pileups with this antenna on 20, 17 and 15. Sometimes I run a SB-200 to even the odds, but most of the time it is not needed.

Am I really losing 10 to 20 dB in the line and tuner? The tuner never gets hot. The SB-200 will keep you warm in the winter though.

Thoughts would be appreciated.

Alex, I'm not sure the fellow you are refering to really understands antennas.
A half size G5RV is OK 40 to 10 but is perhaps 2 to 3 S units below a dipole on 80.

An antenna does not have to be resonant to be efficient or to radiate a good signal.
Resonant antennas really only are important when fed with coax, to minimise losses.
Non-resonant antennas are efficient as long as there is a proper match to offset reactances and match impedance.
You are not losing 10 to 20 dbd with your doublet. I also have similar antenna and it works very well. Fear not, be courteous to jokers like the expert you refer to but remember that many self proclaimed experts only repeat erroneous information they have read or heard, probably on 75 meters.
I claim to only be an authority on antennas because an authority is one who knows a lot of experts.

34136. Re: Antenna question

Yahoo group: ham-antennas (2014)
Date: 2014-09-27 13:51:12 UTC
From: glene77is@...
Topic: 34134 Message: 34136

Alex Netherton, KC4BO (1979)

I run QRP / CW only, mainly 20, often 40.
Ant is an end-fed LongWire, 225' long, at 17' up, via Heath Ant Tuner.
I have trim my LongWire to obtain SWR 1:1.1 on 40 M and 20 M.
Regularly make 1000 miles per Watt contacts to New England.
and sometimes to California or Oregon.
Efficiency is a concern on mine, with not much power to spare.

As I read the ARRL Antenna manual (which I recommend) ,
when any antenna is physically short of the calculated resonant length,
and is tuned into a resonant state by a Tuner,
then current lobe is being balanced by the Tuner.
The portion of the antenna that is being "tuned" to resonance is not radiating.
...
Therefore,
Anything less than a cut-to-length Resonant Antenna
will loose 'some' radiating power.

My conclusion is 'Full Resonant Length is most efficient'.

If I use a 32' EndFed on 40 M, I have a 1/4 wave resonant length of Antenna.
... Most efficient.
If I use a 32' EndFed on 80 M, I have half an antenna actually radiating,
... Less efficient.
Radiation is via via the physical Current Lobe,
... towards this near end of the wire,

Radiation is not via the physical Voltage Lobe,
... towards that far end of the wire.

At Resonance , the Current Lobe looks along these lines, really Peaked I^2

IMO,
If the Antenna is short of a resonant length,
then not all the required antenna length is there.
That is 'inefficient' by some standards.

Thus, the low efficiency of a short Mobile Whip Antenna, BOTTOM loaded.
Thus, the greater efficiency of a short Mobile Whip Antenna, TOP loaded.

My friends, operating QRO toss RF power away in order to have a multi-band GRV.
Very convenient compromise,
but I can not do that at QRP for efficiency reasons.

As an example of handling efficiency:
My friend Art used 600 W into an odd J-pole thing on 40M, only 20' long.

He reported weak signal contacts, unless he runs 600W, on the SSB net.
He recently changed to a Dipole, and his signal contacts jumped up several "S" units.
Same SSB Net.
Same orientation of East/West for the wires across house roof, Same poles, Same height up.
Same distances.

In my experience,
Antennas are a fun thing, and the theory basically works.
There is no magic, just some occasional mysteries.

Hope That Helps.

34137. Conservation of Energy Re: Antenna question

Yahoo group: ham-antennas (2014)
Date: 2014-09-27 17:40:57 UTC
From: Al Bonnyman
Topic: 34134 Message: 34137

Glen,

I'm a new ham. I've been trying to understand what's going on.

There's a fundamental law of physics, the Law of Conservation of Energy: Energy is neither created or destroyed – it's just gets converted. For example, from chemical energy (coal delivered to a power plant) to heat energy (steam) to electricity (in power plant steam turbines) to RF (when it finally gets to your house and your transmitter).

Likewise, when you pump 10 watts of RF power out of your transmitter, it has to be accounted for someway. Assume you've perfectly tuned your tuner (next to the transmitter) to a 1:1 SWR, as I see it that RF energy eventually gets converted in a mix of ways:

1. Turned into heat due to ohmic resistance in your tuner and your feedline.
2. Turned into heat due to ohmic resistance in your antenna. I understand this is usually very low in copper and aluminum.
3. Radiated from your antenna to meet one of several fates:
a. Some of this is absorbed by the ground and converted to heat by ohmic resistance nearby (within one wavelength).
b. Some RF is absorbed by the ground and converted to heat by ohmic resistance over an intermediate distance of several hundred meters (depending on wavelength).
c. The rest radiates out into the distance to ultimately be picked up by (hopefully) others' receivers, bounced around by the ionosphere, absorbed by terrain very far away or sent into outer space to travel forever.

RF energy absorbed by the ground and converted to heat is spread over such a large area that you can't tell heating is going on without sensitive instruments. As I understand it, ground absorption is affected by soil conductivity, radials, antenna height, etc.

The RF energy that doesn't get absorbed by the Earth near your station may or may not go where you want it to go, depending on your antenna. A Yagi produces lots of "gain" but all that really means is that it's focusing all its energy in a narrow beam at the expense of little emitted in other directions; it doesn't actually emit any more energy than an omnidirectional vertical antenna.

Impedance mismatches in the system don't use up any of this energy themselves, but they do cause it to bounce back and forth. In the process, instead of just flowing out one time to the antenna, current may bounce back and forth. While the mismatches themselves don't use up energy, by causing this additional, unnecessary current flow, that extra parasitic current does cause additional ohmic resistance losses in your feedline. The poorer the match between your feedline and your antenna, the more energy is wasted in your feedline; less gets radiated out of your antenna. If you put another tuner between the antenna and feedline to get a 1:1 SWR, this issue goes away.

So my question – if you match stuff up, why would a non-resonant antenna emit less RF than a resonant antenna?

Instead of reduced RF emission, I would think a lack of contacts using a non-resonant antenna would instead be due to:
1. Feedline losses due to impedance mismatches at each end of the feedline.
2. Unexpected radiation patterns (the RF gets out but not in the direction you want perhaps because you didn’t understand the antenna very well).

RF’s gotta go somewhere.

Thanks for helping me with this.

This may help:
http://www.arrl.org/files/file/Technology/tis/info/pdf/q1106037.pdf

A tuner at the antenna will remove the high SWR on the line and thus there is no reflection down the line.

A tuner at the transmitter will match the transmitter to the impedance the line shows it,

The maximum power out of your transmitter will be put out to the antenna.

Yes the antenna may have a different pattern.

A high SWR at the transmitter can cause the transmitters protection circuit to reduce the amplifiers output power but this doesn't mean that power is burned up in the transmitter, just less put out.

You are right, any power that is sent out the transmitter is radiated by the antenna, less any line loss which is a function of line SWR and transmission line length.

David Gillooly

From: L L bahr
Topic: 34134 Message: 34139

Glen,

Who says a non resonant antenna radiates less then a resonant one? Non of my antennas are resonant. Who cares if you are using open wire line with an appropriate "real" balanced line matching device? What is important is where is the radiating taking place and how well placed is this radiation to reach the intended reception of it. (radiation pattern) Reflected power does not go back into the transmitter but again gets sent back to the antenna system.

You obviously are doing some well founded thinking. A non resonant antenna does not have to be less efficient then a resonant one. As you kind of mentioned, a non resonant antenna with an inappropriate feedline may be radiating on the feedline more then on the antenna and thusly appear to be less efficient as it's pattern may not be appropriate for the intended receiving station. Anyone who tells you a non resonant antenna HAS TO BE less efficient then a resonant one doesn't know what they are talking about. For being a new ham, you are doing some well founded thinking!

Lee, w0vt

I recall reading somewhere that there is nothing magical about antenna resonance; it's just easier to analyze.

In theory, I believe that a non resonant antenna would have to be less efficient than a resonant antenna. Consider an antenna that is presenting a 10:1VSWR to an antenna tuner. That would be 70 watts reflected for 100 watts forward power. (10:1 is not unreasonable to expect from some non resonant antennas). That reflected power takes a trip back down the coax, thru the tuner and back up multiple times (infinity in theory). All that equates to loss to the eventual radiated signal. That reflected signal may also be out of phase with the other signals being radiated. The power would be radiated, but it may not add to each other.

Remember all the people who work the world with 1 watt. Empirical testing by hams making contacts does not always equate to true antenna theory. I'm certainly guilty of that.

The reflected power at a 10:1 SWR at 7 mhz with 100 feet of decent coax would be around 30 watts not 70. 1.32 db. Probably not enough to notice a difference at the other end.

http://www.kc7hxc.us/links/radio/Coax%20Calc/Coax%20Calculator.html

Put the antenna tuner at the antenna feed point and there is no swr loss only feedline loss which is usually negligible. The secret is impedance matching for maximum power transfer.

10:1 VSWR with 100 watts forward power would be 66.95 watts, to be exact. This is what the antenna would be reflecting down the feed-line. We were talking about the efficiency of the antenna itself, not the feed-line or the tuner. Any tuner, even at the antenna feed-point, would decrease efficiency of the antenna due to ohmic losses. If losses were negligible manufacturers would not put wattage ratings on baluns and antenna tuners, and DXers wouldn't be burning them up.

Non-resonant antennas can work just fine for the average ham (I have one at my QTH) but I still say that they are not as efficient as a resonant antenna.

Ok ...

Resonant antenna for 80m would be 40m ... right??

But a 50m antenna would have more gain (2x5/8)

And if the reactance at feeding point will be cancelled out (with a series coil at feeding point) you have an antenna that is MORE efficient then your halfwave dipole and the antenna is non resonant without that coil(s)

And if you then let the coils away ... but connect ladderline at that feedingpoint towards that shack and have a OOD balanced tuner there ... then the antenna still is non resonant

And it is still more efficient then your resonant halfwave dipole

...

The resonance of the antenna ... and efficiency of an antenna(system) are complete different kind of shoes

Once again, I'm trying to understand.

If an antenna has more "gain", doesn't that just mean that it focuses more energy in some particular direction (at the expense of less energy emitted in other directions)?

If your 50 meter antenna is actually emitting more RF than your 40 meter antenna, where is that additional energy coming from?

Thanks,

KM4BYJ (new ham)

This is ridiculous! With an effective feedline the reflected power goes back up to the antenna and some/most gets radiated. Then a small amount gets sent down the feedline again and if the feedline is efficient the power again gets sent up to the antenna where some/most again gets radiated. This goes on until the power is so small it is not significant. (Your example of one cycle is only one small part of what is going on.) In short, a non resonant antenna feed with an efficient feedline such as open wire line and then matched with a proper "REAL" balanced line tuner will give you a signal that could not be distinguished from one that was resonant. In actuality, either one could produce a signal at any one receiving point better then the other one. This would be due to the differences in radiation pattern but this has nothing to do with efficiency. (Radiating lobes will be different.) If a non resonant antenna gives you poor results, there is a lot of things wrong with the system other then not being resonant. (I'm talking about antenna efficiency and not which antenna would be best for any one point to point operating situation.) When you are using a non resonant antenna you must use a proper matching unit plus a proper feedline to achieve efficiency. You can't be using a none resonant dipole with a sky high SWR fe d with coax, which is lossy with a high SWR. Nor can you use an unbalanced tuner made into a balanced tuner through the use of a balun configured on the high impedance side of the balancing network. What I have said here is mainly for non resonant antennas which are cut for the lowest frequency oper ated. I'm not talking about some super short antenna which would have a lot of different losses based on how it was configured. (That's another story.) You must also understand to use non resonant long antennas, your matching tuner needs to be really efficient and could p ossibly need to handle some extremely high voltages. This is true even without an amplifier in line as a 100 watt transmitter can generate some really high voltages in a high SWR situation. I operate all over the place with long non resonant ante nnas. I'm in Air Force MARS and our frequencies can be easily 500 kHz above or below the ham bands. No problem with the use of good open wire line and the use of an efficient truly balanced design ed adjustable matching network. My signal is as strong or stronger then most because I have used proper feedline as well as an efficient matching device.

As for the comment on "the average ham", I would say you will most likely find long non resonant antennas are used by "non average hams" more then by "average hams" as they understand what is really going on here. You won't find too many of them using "loaded" dipoles with narrow bandwidths, you won't find too many of them with compromise off center fed antennas with a so so tolerable SWR on a few bands with no tuner or tuner in line such as a G5RV type antenna, and you won't find too many of them having some 4:1 or 9:1 balun in line either at the top or bottom of the feedline. Are all these schemes used in mass? You bet they are. Way too many are being used. They are very popular and pushed by profit motivated dealers to unsuspecting clueless hams. I'm amazed at how many ham s can't or won't even build their dipoles! Do these other antennas work? Sure they do, however a long non resonant dipole fed properly will allow you to go just about anywhere and have a really good signal and you don't have to worry about narrow bandwidth or worry about burning out the balun. Well, I guess many won't worry about permanently changing the properties of their balun with a high SWR because they don't realize this is a potential problem facing them.

Lee, w0vt

"100 watts forward power would be 66.95 watts, to be
exact. This is what the antenna would be reflecting down the
feed-line. We were talking about the efficiency of the antenna itself,
not the feed-line or the tuner. Any tuner, even at the antenna
feed-point, would decrease efficiency of the antenna due to ohmic
losses. If losses were negligible manufacturers would not put wattage
ratings on baluns and antenna tuners, and DXers wouldn't be burning them up."

Non-resonant antennas can work just fine for the average ham (I have one
at my QTH) but I still say that they are not as efficient as a resonant
antenna".

That is exactly what is happening, Al. There is no free lunch. There is no extra power being generated. you are just focusing it like a flashlight beam. There is no extra power. In the case of long antennas which are resonant or non resonant, the lobes produced are different then for say a half wave dipole. Your signal using a longer antenna will thus be stronger in some directions and weaker then in others. The longer the antenna, the more lobes will be produced so you will have more null and peak nodes.

When you are using coax which is lossy when a high SWR is present, it is terrible to use say an 80 meter antenna on 40 meters or a 40 meter dipole on 20 meters. This is because you would be feeding the antenna center point at the high voltage point of the waveform and not at the current portion of the waveform. If you try and install a balun at this feedpoint you will have very high voltages present at the balun. The balun material is easily forever altered into something lossy put under these conditions.

Lee, w0vt

Once again, I'm trying to understand.

If an antenna has more "gain", doesn't that just mean that it focuses more energy in some particular direction (at the expense of less energy emitted in other directions)?

If your 50 meter antenna is actually emitting more RF than your 40 meter antenna, where is that additional energy coming from?

Thanks,

Al,

You can usually use an antenna at it's odd multiple frequencies. That means an 80 meter antenna will work on 20 meters and a 40 meter antenna will work on 10 meters. I say work but understand multiplying bye 3 doesn't always mean the multiplied frequency is where you plan to operate. So if you are using coax, the SWR might be getting high again due to the fact you are not operating exactly at x3 the frequency of the cut antenna. Coax doesn't like high SWR, so the feedline could be becoming lossy again. Feed with open wire line using a matching device would solve this problem. Now, since using an 80 meter antenna on 20 would mean a longer then normal dipole, you would have more lobes and your signal would be stronger in some directions and weaker in others based on the lobe pattern.

> expect from some non resonant antennas).

10:1 SWR at what impedance?

> That reflected power takes a
> trip back down the coax, thru the tuner and back up multiple times
> (infinity in theory). All that equates to loss to the eventual radiated
> signal.

Only if the feedline is such that it can absorb power: such as coax which is operated at other than its characteristic impedance. That problem doesn't exist with open-wire line....at least not to a measurably worthwhile extent.

FYI, in at least one instance I know if, an antenna on a satellite exhibited a 9:1 SWR yet was 98% efficient. To repeat, resonance and efficiency are not related in any way that I am aware of.

> That reflected signal may also be out of phase with the other
> signals being radiated. The power would be radiated, but it may not add
> to each other.

Not true, if it is radiated from the same antenna. "Reflected" from the source (transmitter) is NOT the same as "reflected" from a parasitic element.

The longer antenna concentrates the energy in a smaller lobe

The sum of energy is the same ... just squeezed in a smaller beam

Al Bonnyman, KM4BY

" So my question – if you match stuff up,
why would a non-resonant antenna emit less RF than a resonant antenna? "

To respond to a really good question,
Sounds right. 'They are Not Related Ideas', I would say along with you.
My own antenna example should lend support to your proposition
since I use a Non-Resonant Long-Wire, 225' long, for 40M and 20M.
There is a good current lobe somewhere along that line.
When I switch to 12 foot test antennas, tuned with an Ant Tuner,
I get much poorer SWR and much poorer RST.

I am sure that someone will offer up that a 10:1 SWR can be OK
somewhere and sometime, as far as radiated power is concerned
... but a math proof of that is beyond me.

Employing the Conservation of Energy here may get us off the track.

Agreed, 'CoE' is a real Law, but I don't think that helps here.

IMO,. I would say that the 'same' energy
is building up a magnetic field in the loading coil,
instead of the antenna line.
...

I would say that this is just another RF tuned circuit,
like the Pi-Network we use in Transmitter tuned tanks to couple to the Antenna.
...
Building Magnetic flux in the loading coil (like a RF tuning tank) ? Yep !
Heating up the ground and the wire? Yep !

Trying to run back down the coax shield ? Yep !
Forcing me to use a Current Balun ? Yep !
Conserved Energy ? Yep !

It is far easier to cut a wire to resonance or maybe tune one to apparent resonance
then it is to measure and describe what the mysteries of non-resonant activity are.
...
I find myself in the dark when it comes to what Really happens at Non-Resonance.
I can measure resonance in my audio CW filter circuit designs,
along a " I squared " exponential curve,
but when things get out of resonance , they just don't work good.

I imagine that we are using somewhat different perspectives and wording.
Would like to hear more from you in these forums.

Stay with your thoughts,
and you will go a long way to understanding antenna theory and application.
That is what I am trying to do, nothing else.

Ken Gordon W7EKB
I am with you about 10:1 SWR being hardly any good thing.

It burned up my 807s in my old ARC-5 back in '58.
So, I tried to learn about how to obtain a 1:1
to get things 'apparently' resonating.
I am in the dark about what happens at Non-Resonance.
I design for Resonance, because I can run equations and SPICE
to show the predicted results... particularly at Resonsance.

This 10:1 SWR example is hard to deal with
... throws too much up in the air for a good discussion.
Maybe he needs a little more reference to some theory.

Welcome to the discussion.
It runs counter to the Antenna Theory in the ARRL books.

If your proposal worked,
then some antenna maker would already have one on the market,
and antenna theory would already have been revised.

Good to hear your thoughts.

Have you read anything I wrote?

1. Use coax feed line if the SWR is low if that is your feed l ine of choice.
2. Match the antenna impeda nce to the coax at the antenna feed point. (The only thing I would use here is a coax current choke balun and NEVER a voltage balun as it will have it's properties forever altered due to high voltage which it can't tolerate.)
or
3. Use open wire feed line as it is near lossless unlike coax with a High SWR if you plan to operate the antenna with a high SWR..
4. If you use open wire line, couple it to an impedance matching transformer which many call an 'Antenna Tuner." The tuner should be a true balanced tuner and not an unbalanced one altered with a balun especially if the balun is in the high output side of the tuner.

If you do this, the radio will be happy because it sees 50 ohms. Your power transfer to the antenna will be high because you are using next to no loss open wire line. There is no balun to get burned up and all is well!!!! Everything and everybody is happy. You can go to another frequency and accomplish the same thing by altering the tuner parameters .
You are not locked into a narrow bandwidth. Now, if your tuner is truly balanced, the currents in each wire of the open wire line will cancel each other out and there will be NO RADIATION from the feed line. I'll say it again, THERE WILL BE NO RADIATING OFF OF THE FEEDLINE ! (In reality there might be some radiation from the feed line as the tuner may not actually be balanced nor the antenna either.)

Operating an antenna with coax hooked to an antenna through a voltage balun either at the antenna feed point or at the high voltage end of the tuner is BAD! The voltage balun will have it's magnetic properties forever altered because the core will heat up due to the voltage present. Voltage baluns do no like a high SWR because it heats them up. This will make it lossy. If it gets hot, it's on its way to being destroyed. Coax choke baluns on the other hand don't have this permanent saturation problem. One of the problems with a coax choke balun is the amount of turns required is somewhat frequency specific. (Too many turns can lower efficiency just as too few turns can lower effectiveness.)

This is not magic nor is there any free lunch here. Anything done is at a cost in one form or another. There is no one answer for any problem. Each solution has it's benefits or hindrances. However, there is a best solution for any one set of givens. For example, if you are going to operate just over a few kilohertz, you can then tune the antenna to your center frequency and have a low SWR to your coax and every thing is happy and works just fine. However, you want to operate multiple bands and over a very wide range of frequencies, then a low loss feed line would be better such as open wire line. How much power you are going to run is a decision factor too. If you are running QRP, saturating a core is not much of a factor. Running a 2 KW linear makes this an important factor in what you do and use. I hate G5RV antennas as they work kind of OK on a few bands. Yes there is something better, but it takes better feed line and or more equipment such as a good tuner over none at all or just the use of the limited tuner built in one of the modern rigs.
Tuners cost money. Just remember a tuner at the rig end just keeps the radio happy. If

the feed line is lossy at high SWR, then you efficiency will be reduced because you are not adequately coupling and transferring the power to the antenna. Some of it will go up in heat on the feed l ine or be radiated on the feed line rather then on the antenna. (Sometimes antennas are designed to just this, do some radiating from the feed l ine on some frequencies rather then by the flat top antenna wire.)

I could go on and on, but enough for now. (I could have brought up the cost of tuners, cost of remote antenna matching devices fixed and variable, etc.) I'm worn out!

Ken Gordon W7EKB

I am with you about 10:1 SWR being hardly any good thing.

It burned up my 807s in my old ARC-5 back in '58.
So, I tried to learn about how to obtain a 1:1
to get things 'apparently' resonating.
I am in the dark about what happens at Non-Resonance.
I design for Resonance, because I can run equations and SPICE
to show the predicted results... particularly at Resonsance.

This 10:1 SWR example is hard to deal with
... throws too much up in the air for a good discussion.
Maybe he needs a little more reference to some theory.

RSGB manual states that:

Efficiency= Power Radiated divided by Power Supplied

If power is reflected back due to VSWR (in the case of a non resonant antenna) it is not being radiated as well as a resonant antenna. This will show up as a less efficient antenna. Granted, it will still work fine in many cases, but technically it will be less efficient.

This thread has gone way off subject. The original question was:

"So my question ? if you match stuff up, why would a non-resonant antenna emit less RF than a resonant antenna?"

This is the only question I was answering. I still say that, due to ohmic losses and reflected power, the non-resonant antenna will emit less RF. It may be a very small difference, but it will be less.

I use TESSCO's VSWR & Return Loss Calculator Excel spreadsheet

https://www.tessco.com/yts/knowledge_center/su/xls/rfcalc_3-6-06.xls

Enter Forward Power 100.00 Watts
Enter Reflected Power 66.95 Watts
Calculates VSWR 10.00
Calculates Return Loss -1.74 dB
Calculates Match Efficiency 33.05 %
Calculates Rho 0.82

VSWR has absolutely NOTHING to do with resonance or non-resonance: it
has solely to do with impedance matching. Period.

The answer: It wouldn't.

> This is the only question I was answering. I still say that, due to
> ohmic losses and reflected power, the non-resonant antenna will emit
> less RF.

You are combining too many factors: 1) ohmic losses, 2) reflected power, 3)
non-resonant antenna, 4) RF and a few others which you have only implied
by these such as 5) resonant antennas (by inference from your
"non-resonant antennas") etc..

> It may be a very small difference, but it will be less.

It will not. In point of fact, a non-resonant antenna fed using a properly
matched balanced coupler will exhibit more RF emitted than a resonant
antenna with no or poorly matched feedline.

You are using that spreadsheet incorrectly. There is not one item in it that refers to resonance or non-resonance. It deals solely with MATCHING impedances and what happens when you DON'T match impedances.

Let's examine your question, again, exactly as you;ve asked it.

"If you match stuff up, why would a non-resonant antenna emit less RF than a resonant antenna?"

My (and others') simple reply to that question is: It wouldn't.

Lets take your question apart, examining the ideas inherent in each statement:

1) "If you match stuff up..." This implies several things, among them that you A) Know the impedance of the antenna in question, B) you have matched the impedance of that antenna to the impedance of the feedline, i.e., if the antenna exhibits a 50 ohm impedance, you are feeding it with a 50 ohm feedline (probably RG-8) C) at the transmitter end you are driving that 50 ohm feedline with a 50 ohm output or some sort of electronic unit which changes the output impedance of the amplifier tube or transistor to the impedance of the feedline. D) that due to "...matching stuff up..." there is no loss in the feedline. E) Therefore, every bit of power applied at the transmitter end of the feedline gets to the antenna. F) this implies that all that power will be radiated by the antenna. After all, it has to go somewhere, and there is no loss in the feedline....right?

Hmmm....interesting....so far, there is no mention of resonance...

2) Then you include: "...why would a non-resonant antenna emit less RF than a resonant antenna?"

Can you see that the first statement has zero relationship to this second one?

I repeat: whether an antenna is resonant or not has zero to do with how much RF it emits.

From: L L bahr
Topic: 34134 Message: 34161

True, it will theoretically radiate less, but so much less it would almost be impossible to measure and it certainly would not affect performance. I for one will accept an almost undetectable loss that nobody can distinguish for the ability to operate wherever I want and not be limited to a narrow bandwidth of frequencies. For me, this is a good solution.

This reminds me of the time I was on a reflector talking about building a solid state fun hobby 186 kHz 1 watt experimental band transmitter. Mind you this project was a hobby project! A guy came back to me very seriously and said, "Why don't you build a tube transmitter. Don't you realize in an atomic blast your solid transmitter would most likely fail?" As if I would give a damn about my 1 watt hobby transmitter if an Atomic Bomb went off in my area! What a ridiculous comment.

As for the gest of the topic, I think the poster was interested in the real world. If you want to talk about efficiency, NOTHING is 100% efficient. If you look at all the other alternatives to his question, they too all include inefficiencies!. In my proposal the losses would almost be immeasurable.

I'd like to hear from the poster if he thinks all this chatter is off topic! I see no correlation of the topic to your Tessco's Calculator. In our subject the return loss in the feed line varies with the type feed line used. It is not constant. (Two different feed lines with the same imposed SWR with the same output power will have different power losses.) That calculator appears to be for a particular coax and not for open wire line. No decent open wire line at 100 feet have losses as you show. Most loss figures are shown for 100 foot lengths. dB loss with no length shown is meaningless.

I think what he is suggesting is since the signal imposed on a line with a high SWR has to go up and down the line many times, it theoretically has to have extra copper losses going up and down many times VS going up just once when you have a 1:1 SWR. So yes, MAYBE that is true but insignificant if adequate sized wire is used in a highly efficient feed line. The difference is so small you can hardly measure it and certainly not detect it at a receiving site remote from the transmitter.

However, w hen you have a high SWR that usually means the signal is at high voltage rather then at high current for a given power level. Using ohm's law, losses are less through a wire when a given amount of power is at high voltage rather then at low voltage and higher current. That means in a near loss less open wire line a signal with a given power with high voltage actually gives you less copper loss per 100 foot then a signal with the same power but with low voltage and higher current flowing on it. Thus copper losses in a high SWR condition on a low loss feed line may actually produce less copper loss then if the SWR on the line were lower when the current flowing were higher and the voltage present being lower. (In a low SWR condition the copper losses would be greater per pass but only go up the line once. In a high SWR condition, the copper losses would be multiplied by the number o f significant passes but the copp er losses per pass c ould be less.) In short, I don't think the number of times the signal goes up and down the line makes much difference if any in actual practical efficiency.

Lee, w0vt

PS: I'm done now. I am sure this is boring to many. You are all Chief Engineers of your own stations. Pick out for you stations what you think is best for you. I'm going back to designing an Atomic Bom b Proo f 186 kHz Hobby transmitter!

Line loss for coax is specified as so many dB's per 100 feet (maybe meters) into a matched load. If you know the SWR at the transmitter end then the total line loss can be calculated (Line loss with matched load plus loss caused by higher SWR).

If you have a very long transmission line then losses can add up. Say a 80 foot tower and an additional 100 feet of coax to the shack. If your working QRP with 25 feet of coax it isn't an issue.

Another source of information is here:
http://www.k6mhe.com/files/Reflect_rev1.pdf

Joe , that is nearly true except the 33 watts is probably not all lost but sent back to the antenna in a well matched system. Small loss in the feedline going up initially, reflected back, and again reflected back to antenna. This repeats many times but each time a bit if the signal is radiated.
The actual loss is dependent on the feedline type and the mismatch.
Many calculators are simplified and are thus a bit inacurate.
Maxwell covered this very well in his book "Reflections".

True, we agree. The loss in the wire may be considered to be insignificant, but what about the devices we use to obtain a match? Baluns, toroids, coils, etc all can get warm or sometimes very hot. This burns up power as heat that is not radiated by the antenna, therefore reducing antenna efficiency. Ask a DXer who has burnt up one of these devices, they can dissipate lots of RF power.

People, I am only referring to antenna efficiency, as defined in the RGSB handbook. This doesn't factor in radiation pattern, etc. It only calculates the ability to transfer power to the air, not how well the antenna performs. I didn't write the calculation, so please don't shoot the messenger.

True, we agree. But what about the losses in the matching devices I stated in my previous email? The original question asked about efficiency, not how much efficiency. Whenever power is lost efficiency goes down. Maybe just a little, maybe a lot.

34168. Re: [ham-antennas] Conservation of Energy Re: Antenna question

Yahoo group: ham-antennas (2014)
Date: 2014-09-28 03:51:17 UTC
From: L L bahr
Topic: 34134 Message: 34168

I think all this was mentioned and covered, Joe. I've mentioned ferrite voltage baluns at the feed point of the antenna as well as their short comings. I've mentioned the losses connected with making an unbalanced tuner a balanced tuner using a ferrite baluns and the need to use a real balanced antenna tuner when using open wire line. I think I mentioned antennas with loading coils present losses and restrict bandwi dth. I think radiation patter ns are another topic. but they were slightly covered too. In short, for high efficiency, use low loss line or keep the SWR down as much as possible if coax is used on the coax. SWR can mean nothing when using open wire line properly. Don't use voltage baluns in high voltage or high SWR conditions, don't use loading devices unless you can live with narrow bandwidths and have no other alternatives, and also I mentioned heat loss due to mismatch not only creates loss but permanently alters properties of ferrite. How were these things not covered? What is important to me is how to get as much power fed and transferred into the expected radiating surface from the transmitter with the methods to do so at my disposal and budget.

Lee, w0vt

34171. Re: [ham-antennas] Conservation of Energy Re: Antenna question

Yahoo group: ham-antennas (2014)
Date: 2014-09-28 04:15:34 UTC
From: L L bahr
Topic: 34134 Message: 34171

Antenna tuners or better described matching devices all have their good and bad points. They range greatly in what they can do and in cost. Their efficiencies very greatly too . Studies have shown the old Johnson Matchboxes get about as good as you can expect at around 90% efficient. The frequency used for the test affects efficiency of the tuner too. How versatile and how much power they can handle also affects performance. Most tuners sold today are actually unbalanced tuners and when used for balance applications have a toroid balun placed at either the input or output end of the tuner. Placing a ferrite balun at the output end is a bad thing as it sees high voltage and ferrite baluns are bad news under this condition unless we are talking about low signals or QRP. (The properties of the ferrite change as they heat up due to high SWR.) Since the topic was efficiency I've been stressing the use of open wire line for antennas to be used over entire bands rather then one specific frequency. To use such line, you need to have a real balanced tuner for efficiency sake. That means a balanced tuner without the use of a ferrite balun . If the balun is at the output of the tuner it is easily saturated and forever destroyed. Then if it is placed at the input, it is almost impossible to have a true really balanced condition on the balun's output. Since this is almost a certainty, the current flow going up and down the ladder line will not be equal, this means the feed line will do some radiating. (Sometimes this is what you want but in most cases this is not what you want to happen.) If you have open wire coming into the shack and the current is not balanced, the radiation can get into TVs, stereos and telephones. Thus you want a good balanced tuner of good design without the use of baluns and you want the tuning to be indeed balanced. The best bang for the buck is an old Johnson Matchbox but they don't cover the WARC bands or 160 meters unless altered. Otherwise you really have to build from scratch a good balanced tuner. (The MFJ balanced tuner doesn't have a lot of range.)

Lee, w0vt

Joe , that is nearly true except the 33 watts is probably not all lost but sent back to the antenna in a well matched system. Small loss in the feedline going up initially, reflected back, and again reflected back to antenna. This repeats many times but each time a bit if the signal is radiated.
The actual loss is dependent on the feedline type and the mismatch.
Many calculators are simplified and are thus a bit inacurate.
Maxwell covered this very well in his book "Reflections".

If you want some cast-iron nuances, I recommend "Reflections III" by Walt Maxwell W2DU(SK). (Don't bother with I and II, those are editions, not volume numbers.) It can be obtained at:

http://store.cq-amateur-radio.com/Detail.bok?no=183

Forty clams (about a bag of groceries in this troubled age) won't kill you. I survived, and I live on SS. You might find a used copy. Hams are killed by other things (not books), then their widows sell their stuff. (Or sometimes, I hear, destroy it out of spite.) For a laugh, look it up on Amazon.

Problem with this book is that there are those who doubt him. Not being a MSEE, I have no (credentialed) opinion. W2DU's resume, however, is impressive. Warning #1, Walt is "out of print", and CQ Mag might fold any day. (They're on our side, and could use the business.) Warning #2, the book may have "math" and (heaven forfend!) the dreaded Smith charts. Warning #3, CQ also sells Sevick's stuff about baluns. Yet another controversial book by an SK, W2FMT in this case.

This topic, transmission lines, is about as on-topic as it can get.

One other thing as I was asked this privately off the reflector. The question was why can't you use an antenna at it's even multiples such as an 80 meter dipole on 40 meters. The truth is you can use an even multiple antenna on even multiples. There is no electrical reason why it won't work nor not work well. The reason why it is frowned upon is you are now feeding the antenna at a very large or the largest voltage point on the antenna and this creates the need for an antenna matching device which can handle these extremely high voltages as well as the need for better feed l ine insulation between wires. The tuner would also have to be able to tune out this greater presented reactance . (It would be insane trying to do this with coax!) Tuners like this would cost much more to manufacture and may not be available. Even 100 watts produces high voltages with this type configuration. Now install a high power amp and you better have a BIG tuner and decent feed line and also insulated from other structures! Other then this , there is no reason why you could not use an even multiple dipole with a good low loss line such as open wire ladder line. A good friend of mine, W5MP temporarily installed an 80 meter dipole a few weeks ago and temporarily ran the commercial ladder line into his shack over a few bushes. Using the antenna with his Drake L-4B on 40 meters, the bushes caught on fire. The plastic covered ladder line could not handle the extreme voltage placed upon it. He has since constructed home made open wire line and his problems went away. The insulators no longer get hot or even warm. (He is using a just completed home made balanced line tuner. The parts to build it cost somewhere around $1750 dollars. It takes the voltages presented to it with no problem on even multiples of half wavelengths.) Forget trying to do this with a built in rig tuner or some weak MFJ tuner. So the bottom line is most hams won't want to fool with these requirements and thus it is a good idea to stay away from even multiples unless you want to handle the requirements a nd the possible extra costs involved.

Think of a balloon.

Blow the balloon up and you have a fixed volume. Now think this is the total energy output or lets say 100 watts.

Now squeeze the balloon around such that you point it in a specific area you are concentrating the output in the area and also concentrating incoming signals.

Like the reflector in a headlight you point all the light where you want it going down the road.

Energy is the same but you mold and concentrate where you want it to go.

The longer antenna concentrates the energy in a smaller lobe

The sum of energy is the same ... just squeezed in a smaller beam

A quick search of the ARRL website found this:

<http://www.arrl.org/transmatch-antenna-tuner>

"With proper system design, an antenna tuner or transmatch can allow a non-resonant antenna to operate nearly as efficiently as one that is carefully cut to resonance."

If the ARRL is correct, the resonant antenna is more efficient that a non-resonant antenna. Granted, the difference can be small, but there is a difference that favors the resonant antenna.

I've used non-resonant antennas for years and they have worked just fine, but a resonant antenna would give better efficiency. Maybe not much, but better.

Well, that would be true for antennas in space with no nearby dielectrics, and is difficult to determine the amount radiated. We live on earth and next to lossy ground and nearby trees, etc. The power radiated can be absorbed in those nearby objects and is therefore not radiated into space let alone the direction we want, but the antenna efficiency may be quite high. So I tend to favor the use of antenna efficiency defined as the ratio of the radiation resistance divided by the radiation resistance plus all associated loss.

η = Rr / (Rr / Rl)

The Rl contains the sum of all loss such as ground (earth) loss, conductor loss (copper/aluminum loss), dielectric loss, matching component loss and other loss I'm forgetting here.

Bottom line: we have to be careful when we define efficiency and where we draw the circle around "the system" as my physics professor said. If we were to draw the circle around just the antenna, many antenna designs currently commercially available today would be very efficient, but bring that antenna next to earth or in the middle of some trees and the efficiency is reduced.

Now, how much reduction in efficiency? That can only be calculated and never measured directly (at least I know of no anechoic chambers for HF with ground and trees in them). It can be measured indirectly by using data from calibrated test equipment to determine input impedance and backing out theoretical values of loss and arrive at an efficiency that will be close. For example, we put up a 1/4 monopole for 20 meters that measures approximately 16.5 feet long made of 1" aluminum tubing and drive a one ground rod. We take our uncalibrated SWR meter and measure 1:1 SWR. Perfect, we think. When we look at the efficiency formula, Rr is 36 Ω and since we have obtained a 50 Ω reading on our meter we must have 14 ohms of loss to get to that 50 ohm meter reading. Putting these numbers in the formula we get 36/(36+14) = 72% or (10Log(0.72)) = -1.42dB loss in heating the ground. But let's say the denominator is higher due to higher loss. We measure a 2:1 VSWR at the feedpoint and see the R value to be 100 ohms. What then? Well, same formula, different result. 36/100 = 36% or -4.4dB! That's why it is ALWAYS better to drive down loss by adding more radials than just one or two. And since we are using uncalibrated test equipment there are many sources of error in the measurements. If you put two dummy loads in parallel and connect it to your meter you should see 25 ohms, if not, there is one source of error.

It gets worse for the so called "halfwave" antennas, end fed antennas that are only 16 feet long and fed in a voltage mode on all bands. First of all, how long is a halfwave antenna? Who's buried in Grant's grave? A halfwave antenna is only a halfwave at one frequency, the rest are longer or shorter. So if you were to calculate the efficiency of that same 16.5 foot piece of aluminum fed at the bottom for 40 meters and elevated up off the ground and maybe the ends had capacity hats to "increase" the efficiency, we can prove that the efficiency would be less than the 1/4 wave monopole outlined above because the Rr would be considerably less and the loss from the capacitive coupling of the hatted vertical dipole would couple energy into the ground, thus increasing the loss component and decreasing efficiency . These examples are a recap from a two part pdf found online called, "Dirty Little Secrets" parts 1 and 2. The engineering is sound and is written at an easy to understand level.

OK, so we seem to agree on the basic theoretical antenna. My claim is that VSWR created by a non-resonant antenna is going to create losses that are going to reduce the radiated power of the antenna, thereby reducing overall efficiency of the antenna. Theoretically, do we agree?

(I didn't make this theory up, it's from the book).

Joe.

Joe,

You can have a very high input impedance to a given antenna system and if you have a very efficient high Z conjugate match, the losses will be the same for an equally designed low impedance match, the end fed halfwave matching circuit can have an efficient transfer of power if properly designed.

The very high SWR alone does not mean poor efficiency. You have to identify the losses within the antenna system and factor those into the efficiency ratio.

The highlighted statement below needs to have this inserted... "for a low Z antenna system fed with a low Z matching system".

The transfer of power (efficiency) can be the same if the matching circuits are designed to their respective impedances. Such as a high Z load with a high Z match equals a low Z load and a low Z match if all other things are equal.

I agree, but we are starting with a 50 ohm impedance from the average ham transmitter so matching is going to cause some loss, however insignificant it may be.

Oh sure. I should have said low z to high z matching. In any case, careful attention paid to loss in the matching system can produce efficient transfer of power.

Indeed.

Another assumption being implied here is that all non-resonant antennas
automatically exhibit high to very high SWR, while all resonant antennas
exhibit much lower SWR: this is not necessarily the case.

In any case, it is the SWR on the feed-line, or within the impedance
transformer(s) (coupler/couplers) that is the primary cause of "losses".

No. Again, your terminology is not precise enough. As I just stated, the primary cause of ineffeciency in antenna systems is in whatever mechanism is used to couple the transmitter's output to the antenna.

This can include both the feed-line and any impedance-transformers in the circuit.

Since coax became the defacto standard for coupling the transmitter to the antenna (whether or not there is/are impedance transformers in the circuit) THAT, coax, has become the primary place where losses and therefore ineffeciencies of the antenna SYSTEM occur.

> (I didn't make this theory up, it's from the book).

Then you are mis-reading the theory: you say: "...that VSWR created by a non-resonant antenna IS GOING TO create losses that are going to reduce the radiated power of the antenna,..."

If you had said: "..that VSWR created by a non-resonant antenna ***CAN*** create losses that are going to reduce the radiated power of the antenna...", I would agree with you, since this is not always the case.

But again, those losses are primarily caused by whatever mechanism you must use to couple the transmitter to the antenna.

The antenna itself is simply a load, like a big resistor, and its efficiency is not determined by whether or not it is resonant.

OK, I'll agree with that if you can give an example of VSWR being
present without any losses occurring. That part I don't understand.
I'm not trying to be sarcastic, I just can't visualize VSWR happening
without losses in the system.

VSWR is not created by non-resonant antennas. It is created by
impedance mismatch. That is not sophistry or "theoretical". It
makes a difference.

Here is a resonant antenna with plenty of VSWR:

Antenna: folded dipole, resonant with feedpoint impedance of 300 ohms.
Feedline: 300 ohm twinline of any length.
--or--: 1/2 wavelength of any feedline.
Transmitter: 50 ohm output impedance.

Here is a non-resonant system with VSWR = 1:

Antenna: impedance at feedpoint R + jX for any values of R and X
Feedline: 1/2 wavelength, of any characteristic impedance whatsoever.
Transmitter: output stage of R - jX impedance.

These are both very real possibilities, not pathological at all.

Notice that there is a theorem in E.E. that proves that maximum
power transmission from source to load occurs when Zsource = Zload*,
i.e. when Zsource is the conjugate of Zload, i.e. Rsource = Rload
and Xsource = -Xload. Did I say something about VSWR here? No.

Really, Joe, you need to read and understand what is written, not what you think it should say. Neither I nor anyone else here ever said that VSWR....ON THE FEEDLINE...did not incur losses: you asked about the ANTENNA, but appear to be ignoring the system that couples the antenna to the source.

VSWR is measured on the FEEDLINE, not on the antenna itself.

There are ALWAYS losses through the SYSTEM which couples the transmitter to the antenna, AND if the VSWR is "high", then all the losses occur in the FEEDLINE.

If that FEEDLINE is coax, those losses can be very high. These high losses in the FEEDLINE and COUPLING system will, of course, reduce the OVERALL efficieny.

But again, none of these have anything at all to do with whether or not the antenna is resonant.

Why do you think that Lee and I keep harping on open wire line?

There's always heliax...

Heh heh. This is another example of a non-resonant antenna being
more desirable than resonant. Easier to tune.

The love of resonance comes from the nasty way that certain organizations
encourage the use of VSWR as the sole figure of merit of an antenna
"system". Actually, nobody talked much about VSWR before solid state
output stages, which is also when manufacturers stopped building what
amounted to heavy duty tuners into radios. Made them compact and could be
painted black and masquerade as military equipment, I suppose.

> Tuners like this
> would cost much more to manufacture and may not be available.? Even
> 100 watts produces high voltages with this type configuration.?

It seems to me to be more a question of size and attentive design.
Old (Johnson etc) tuners were not large because men craved clubby,
ungainly equipment, but because the usual tuner components need some
space. (To avoid stray capacitance and sometimes even arcing). They
still do, the laws of physics having remained remarkably constant.
(It's obvious you, Lee, know this.)

Hmmm. Since really good coils can be had fairly cheaply or made fairly easily, (especially if one has a machine shop in the cellar) I assume W5MP is using vacuum variables, sync'ed and driven by servo motors of some kind? Probably also a large box and connections made from copper sheet or better, silver-plated copper sheet. I guess I'm asking which circuit he chose.

Is it something like a Kilowatt Matchbox bulked up a bit and modded to cover the WARCs? (Kids who don't know the KW Matchbox -- it'll handle about 3 of the wimpy KWs we use nowadays on the usual antennas. It looks like a "small" 100W (i.e. 300W in practice) Johnson Matchbox, which is no toy itself, about a 10"/250mm cube, but BIGGER. Big (widely spaced for voltage, big plates for capacitance) capacitors in there. Now around 50 years old, they go for around 3-400$ on Ebay, and they are not just for "antique collectors". There's a German variation on the Matchbox circuit that is superior. There's an article by Cebik on the subject.)

Just a teaser: I've recently stumbled across an actual "unbalanced" balanced tuner, i.e. one that tunes each branch independently, good for things like asymmetrically fed antennas. It's an RSGB design. (kids: OCF dipoles may have an "input impedance", but each arm is different. Hence ladder-feeding an OCF will either cook a balun or radiate from the line, due to a common mode current. Coax will have currents on its "third wire", for that matter. So I think, anyway.)

In this thread, you all have noted that baluns can be magnetic damaged by excessive heat.

Assuming either there's no damage to the wiring or that any such damage is repairable:

Is it possible to somehow restore the Balun magnetically? That or work around its change in magnetic state (changing turn count, etc.)

Thanks,

Al Bonnyman

I have never heard of an antenna tuner with a fan or blower.
There almost no losses in the coils or capacitors, save IR losses in the conductors.

Tough question because there are too many variables to consider. In the case of a properly designed balun matched into a purely resistive load one can obtain loss measured in tenths of a deciBel. However, loss can be in the 10-20 dB range if a highly reactive load is attached.

Loss in tuners is hard to determine too because the loss mechanisms are conductor loss, dielectric loss, circulating current loss, the list goes on. However, a properly designed tuner can exhibit low loss in tenths of dB to several dB on the high end.

Al,

Ferrite material has a high temp limit of the published Curie temp. Going above this temp can cause the magnetic (probably missing some other magnetic name such as paramagnetic, diamagnetic, or ferromagnetic term) property to be changed. To what degree? Who knows? I've never gotten any that hot to experiment with. However, iron powder cores are much hardier and can handle much higher flux density for a given temperature rise.

The reason iron powder cores are popular is that when you wind an inductor on an iron core you can calculate the exact value and usually be spot on when you measure the inductance. Not true of ferrites. Wind two identical inductors on two identical cores and you'll end up with two different values of inductance. It's because the consistency and accuracy of the mix in iron power cores are tightly controlled and is not controlled for ferrites. So you get what you get.

Another neat property of these materials, both the iron powder and ferrite cores can be glued back together in case they fracture and break apart without affecting their performance. In fact some Baluns don't rely on the complete path inside the core to work. Hence the transmission line transformer effect where it's the electric loading on the transmission line wound on the core that makes them unique compared to traditional flux coupled transformers. I seem to remember a G0 call running some tests on a Ruthroff wound 4:1 voltage balun missing 1/3 of the core and the performance was unchanged. Neat.

High swr on ladderline is no problem (if you can match the load at shack end)

High swr on coax = high losses on feedingline

That is to make a long story short

So ... if you wanna use coax ... then use an antenna setup that has low swr on your bands you wanna use our antenna (or in other words make it resonant on these bands)

If you use ladderline you can use any length of antenna on any band (with a proper designed balanced tuner in the shack) ... and have low losses on your overall system

And then you can play with different lengths of antennas and different lobes of the harmonic bands ...go figure why some use ladderline ... low loss in the overall system and multiband use (without lossy traps etc.)

If anyone mentioned this I missed it. The reason coax isn't good for high SWR antennas is due to the fact that coax has a continuous dielectric separating the inner conductor from the outer conductor (shield). All dielectrics have a "dielectric coefficient" which essentially is how much RF that dielectric will absorb and turn into heat. Air has a dielectric coefficient of "1" and plastics have a dielectric coefficient of more than 1 and it varies with the particular plastic. All dielectrics will turn some of the RF into heat at any SWR, at any power level and at any frequency. The conversion of RF into heat increases with frequency and SWR and, of course, more heat at higher power levels. Ladder line has air as the dielectric with spacers (spreaders), usually plastic or sometimes wood, spaced along the length of the line. The spacers make up such a small percentage of the dielectric that you can essentially consider ladder line as having air as the dielectric. At any SWR, ladder line is more efficient than coax. However, in the real world, coax losses at relatively low SWR are acceptable especially when you consider that coax is readily available, relatively inexpensive, has an impedance that matches the output of common radios and many types of antennas both commercial and homebuilt, can be routed without consideration of nearby metallic objects and is just plain "handy" with many types of readily available connectors. Also, coax comes in many flavors and using high quality coax of larger diameter with high quality dielectric and keeping the coax run as short as possible minimizes losses.

Ladder line does have it's place in our hobby as it does allow many types of antennas to be operated efficiently on many different bands of frequencies where coax losses would make it's use impractical.

Subject: Re: [ham-antennas] Conservation of Energy Re: Antenna question

I think what he is suggesting is since the signal imposed on a line with a high SWR has to go up and down the line many times, it theoretically has to have extra copper losses going up and down many times VS going up just once when you have a 1:1 SWR. So yes, MAYBE that is true but insignificant if adequate sized wire is used in a highly efficient feed line. The difference is so small you can hardly measure it and certainly not detect it at a receiving site remote from the transmitter.

However, when you have a high SWR that usually means the signal is at high voltage rather then at high current for a given power level. Using ohm's law, losses are less through a wire when a given amount of power is at high voltage rather then at low voltage and higher current. That means in a near loss less open wire line a signal with a given power with high voltage actually gives you less copper loss per 100 foot then a signal with the same power but with low voltage and higher current flowing on it. Thus copper losses in a high SWR condition on a low loss feed line may actually produce less copper loss then if the SWR on the line were lower when the current flowing were higher and the voltage present being lower. (In a low SWR condition the copper losses would be greater per pass but only go up the line once. In a high SWR condition, the copper losses would be multiplied by the number of significant passes but the copper losses per pass could be less.) In short, I don't think the number of times the signal goes up and down the line makes much difference if any in actual practical efficiency.

Lee, w0vt

PS: I'm done now. I am sure this is boring to many. You are all Chief Engineers of your own stations. Pick out for you stations what you think is best for you. I'm going back to designing an Atomic Bomb Proof 186 kHz Hobby transmitter!

VSWR has absolutely NOTHING to do with resonance or non-resonance: it has solely to do with impedance matching. Period.

The answer: It wouldn't.

> This is the only question I was answering. I still say that, due to
> ohmic losses and reflected power, the non-resonant antenna will emit
> less RF.

You are combining too many factors: 1) ohmic losses, 2) reflected power, 3) non-resonant antenna, 4) RF and a few others which you have only implied by these such as 5) resonant antennas (by inference from your "non-resonant antennas") etc..

> It may be a very small difference, but it will be less.

It will not. In point of fact, a non-resonant antenna fed using a properly matched balanced coupler will exhibit more RF emitted than a resonant antenna with no or poorly matched feedline.

> I use TESSCO's VSWR & Return Loss Calculator Excel spreadsheet

> Calculates Return Loss -1.74 dB
> Calculates Match Efficiency 33.05 %
> Calculates Rho 0.82

You are using that spreadsheet incorrectly. There is not one item in it that

refers to resonance or non-resonance. It deals solely with MATCHING impedances and what happens when you DON'T match impedances.

Let's examine your question, again, exactly as you;ve asked it.

"If you match stuff up, why would a non-resonant antenna emit less RF than a resonant antenna?"

My (and others') simple reply to that question is: It wouldn't.

Lets take your question apart, examining the ideas inherent in each statement:

1) "If you match stuff up..." This implies several things, among them that you
A) Know the impedance of the antenna in question, B) you have matched the impedance of that antenna to the impedance of the feedline, i.e., if the antenna exhibits a 50 ohm impedance, you are feeding it with a 50 ohm feedline (probably RG-8) C) at the transmitter end you are driving that 50 ohm feedline with a 50 ohm output or some sort of electronic unit which changes the output impedance of the amplifier tube or transistor to the impedance of the feedline. D) that due to "...matching stuff up..." there is no
loss in the feedline. E) Therefore, every bit of power applied at the

transmitter end of the feedline gets to the antenna. F) this implies that all that
power will be radiated by the antenna. After all, it has to go somewhere, and
there is no loss in the feedline....right?

Hmmm....interesting....so far, there is no mention of resonance...

2) Then you include: "...why would a non-resonant antenna emit less RF than a resonant antenna?"

Can you see that the first statement has zero relationship to this second one?

I repeat: whether an antenna is resonant or not has zero to do with how much RF it emits.

10:1 VSWR with 100 watts forward power would be 66.95 watts, to be exact. This is what the antenna would be reflecting down the feed-line. We were talking about the efficiency of the antenna itself, not the feed-line or the tuner. Any tuner, even at the antenna feed-point, would decrease efficiency of the antenna due to ohmic losses. If losses were negligible manufacturers would not put wattage ratings on baluns and antenna tuners, and DXers wouldn't be burning them up.

Non-resonant antennas can work just fine for the average ham (I have one at my QTH) but I still say that they are not as efficient as a resonant antenna.

Again, absolutely correct. Coax is just plain "handy". Ladder-line is very often
VERY "un-handy".

> Ladder line does have it's place in our hobby as it does allow many
> types of antennas to be operated efficiently on many different bands of
> frequencies where coax losses would make it's use impractical.

Yes. Exactly.

Trying to use coax with a NON-RESONANT antenna is VERY difficult.

One must use all manner of strange methods, baluns, etc. to match a
NON-resonant antenna to a transmitter if you try to use coax. In fact, I don't

know of any method to use coax with a NON-resonant antenna which will work over more than one band at once.

And due to the necessity of using these "strange" methods, there is usually far more loss in the coax feed-system than if one used ladder-line and a balanced impedance transformer (coupler).

VSWR on ladder-line makes almost no practical difference whatever: VSWR on coax, makes a HUGE difference. High, and even HUGE VSWR on ladder-line exhibits no noticeable loss. Moderate VSWR on coax can exhibit substantial loss.

However, using ladder-line, and a balanced-coupler allows the average ham to use a NON-resonant antenna and achieve the same, or better, efficiencies as a resonant, properly built, coax-fed antenna could exhibit.

As I have been trying to say for the past couple of days, the only real problem with non-resonant antennas vs resonant antennas is the problem of feeding them: transferring the RF from the transmitter to the antenna with minimal loss.

ALL the losses occur in the feed-system.

Any "loss" that occurs in the properly-matched antenna itself is simply radiation of the RF, which is simply useful "work".

BOTH coax, AND ladder-line have their places, and where you can use one to good effect, it may be impossible or at least impractical to use the other.

wrote:

> How bad are typical losses for baluns and tuners?

As others have said, it depends on the design and construction of either. For instance, if you attempt to use a tuner designed for 100 watts to run a KW through, if you don't burn up the tuner, the losses will be very substantial.

Also, poorly designed tuners can exhibit terrible losses, even if built with high power components.

USUALLY (note that word) the larger and heavier the components, the wider the capacitors are spaced, or perhaps expensive vacuum capacitor are used, and the larger and more perfectly-made the "joints", the lower the losses....but this is not always true either.

> Is there anything, loss-wise, that I should be aware of in buying, building or

From: Al Bonnyman
Topic: 34134 Message: 34207

Ok, I have another "new ham" question for those of us using coax.

If I have a wire dipole for one wavelength and I use it on another wavelength, I can get a sizable SWR at the antenna-balun-feedline junction resulting in significantly increased feedline losses. A remote antenna tuner can fix this but the tuning will vary across a given band.

I also understand that a remote antenna tuner adds cost and complexity to my station - is that true? (I've got kids in college - money's tight!)

So what I'm wondering is: can I set up an arrangement of locally manually tuned inductors and capacitors at the antenna, then walk outside and tune them for a close-ish match for the whole band to get a lower, but not optimum SWR at the antenna? This could potentially reduce but not totally eliminate my parasitic feedline losses.

I'd still use a regular tuner at my transmitter.

Thanks,

Al Bonnyman
KM4BYJ

P.S., thanks for you all answering the questions I've been asking.

OK. I am a FIRM believer in the KISS principle: in this case, eliminate the
unnecessary: the remote coupler.

My suggestion to you is that you use a "fan-dipole". This antenna is featured
in almost all issues of the ARRL Antenna Book.

It uses one coax feedline, yet is useful on mulitple bands, and if properly
made and installed, needs no antenna coupler.

Basically, it is a series of dipoles cut for the various bands on which you wish
to operate, all tied together and fed in the center (preferably with a good
current balun) with 75 ohm coax, RG-11.

The legs of the various dipoles are "fanned" out from one another at the far
ends.

Others here will have more and better info on this for you.

It has been suggested to me by two independent people that I investigate the K9AY loop as a possible help for my really terrible local noise problem, especially at MF. (FYI, I am a member of a group using an experimental license at 630 meters)

After doing some web-research on this antenna, I have a couple of questions:

1) Can it be used or modified to be used for transmitting?

2) Is there any advantage to using it for transmitting?

3) If I already have a transmitting antenna (a 55' tall vertical) how far away from that antenna should I mount the K9AY loop(s)? (Obviously, as far as possible, but what is the minimum separation required?)

4) How important is it to have a "radial field" under each downlead?

5) It appears from my reading that the K9AY loop is useful primarily for MF, or low HF, and not really for frequencies much above 7 MHz. Is this correct?

6) Has anyone here used one, and if so, what were your results?

100-125 ft.

QRP power initially. Maybe 30 watts later next year after I build a small amp.

SSB initially, CW once I learn Morse.

Not going to exactly saturate the ether at this power.

Maybe 100 someday (after kids out of college).

So every db counts at these levels.

Al,

I live in town and my enjoyment with ham radio is noise limited on receive. Meaning, I had an all band, 160-6 meter random wire end fed and tuned with an SGC-230 tuner and thought life was good until I started participating in QRP fox hunts on 40 and 80m during the winter last year. I couldn't hear them with my setup. I had all band coverage but if you can't hear them, you can't work them. So I was forced into engineering a new solution. I built a magnetic loop (for receive only at first) and walked around the yard to find the quietest spot on receive, and direction noise was coming. That exercise has paid dividends beyond my imagination. Who knew? I do now and would recommend doing something similar in anybody's situation. I found a neighbor whose house was emitting a rushing, pulsed noise and when I built a single element Quad, I oriented it away from that noise source. I put that SGC-230 tuner (yes, I know money is tight) right out at the feedpoint and it was the best investment of time ever spent on an antenna system. My loop is approximately 77 feet long, equal length sides, the top at 36 feet coming down to the tuner at 9 feet up on those green fiberglass army camo poles. I stretch out the corners with more green poles and this thing really works well (meaning decent gain, 6-8dBi) on 20-10m and marginal on bands below 30m. I usually ran a dual band vertical for 40/80, but this year I modeled, in EZNEC, a way to feed one end of that quad and put up two 28 foot wire counterpoises at 180 deg from each other in the direction of the 20m quad radiation, (not in the plane of the antenna but orthogonal to it), 9 feet up off the ground. The tuner output connects directly to one end of the quad wire and the other end of that 77 foot piece I leave open. The counterpoise connects to the tuner's ground. The whole thing is a vertical on 40/60/80/160m and we will see how it plays on the QRP foxhunts this year, and maybe an indoor contest or two. BTW, contests tell you if your antenna is working or not. I can run it on the higher bands as well but at a sacrifice of all the gain.

Good luck Al with what ever you choose. Just make sure you locate it away from the house (noise source).

Actually it is easier than that, you can simply add a (coiled) length
of feedline to the output of your tuner for each BAND, the common
lengths (for a set) were on the www.cebik.com website before L. B.
Cebik, W4RNL went SK, now I don't know.

How hard and expensive is it for new hams to build an antenna tuner for use at their transmitter for use with an unbalanced line?

How about a remote tuner? If I bury coax in plastic conduit out to the center of my yard to feed a dipole overhead, does it make more sense to power it off its own low voltage power line run in the conduit or to power it off DC on the coax jacket. I'm guessing it doesn't take much power to run something like a little DC motor to turn a variable capacitor.

I'd probably bury 100+ feet of coax out to the center of the yard then ladder-line from there to a wire antenna.

David,

Mostly I was asking this as a general question (I'm a new ham).

Initially I'm looking at burying 100-125 feet of coax to the middle of my backyard, then ladder line up to a wire antenna.

I have domestic concerns running ladder line all the way back to my back deck.

Al,

Well, it's not hard but there are some nuances that need attention. I liken it to replacing the water pump in a car, not hard once you know how but if you don't know how, it's considerably harder. But you are absolutely right, go for it. We will be here to guide you along the way of your journey. In fact if you choose quality components and correct design, it can be more efficient than some commercial offerings.

Ron,

Thanks for the good idea. I like "simple".

Question for folks:
You have to pay for access to the Cebik site -- is it worth it?

Note that, while money's tight I've actually bought and read multiple books since I got sucked in this hobby in May. Learning, planning and figuring is interesting to me. I've learned it makes financial sense, too -- kind of like "measure twice, cut once."

Yes. Exactly.

Trying to use coax with a NON-RESONANT antenna is VERY difficult.

One must use all manner of strange methods, baluns, etc. to match a NON-resonant antenna to a transmitter if you try to use coax. In fact, I don't
know of any method to use coax with a NON-resonant antenna which will work over more than one band at once.

And due to the necessity of using these "strange" methods, there is usually far more loss in the coax feed-system than if one used ladder-line and a balanced impedance transformer (coupler).

VSWR on ladder-line makes almost no practical difference whatever: VSWR on coax, makes a HUGE difference. High, and even HUGE VSWR on ladder-line exhibits no noticeable loss. Moderate VSWR on coax can exhibit substantial loss.

However, using ladder-line, and a balanced-coupler allows the average ham to use a NON-resonant antenna and achieve the same, or better, efficiencies as a resonant, properly built, coax-fed antenna could exhibit.

As I have been trying to say for the past couple of days, the only real problem with non-resonant antennas vs resonant antennas is the problem of feeding them: transferring the RF from the transmitter to the antenna with minimal loss.

ALL the losses occur in the feed-system.

Any "loss" that occurs in the properly-matched antenna itself is simply radiation of the RF, which is simply useful "work".

BOTH coax, AND ladder-line have their places, and where you can use one to good effect, it may be impossible or at least impractical to use the other.

It is simple to build if you have mechanical ability and a shop. I have no electronic brain power but a building background, retired tool maker / machinist and a small work shop. Buying all new parts can get very expensive, picking up stuff at hamfests makes it fun and cheap. I do know that having things out side can be a nightmare with condensation. My first baluns were not sealed/vented properly and developed moisture after a full season. I am lazy so I just put up a loop and use it.

Rich,

Thanks for the comments. That's useful information about condensation and moisture.

Unfortunately I don't have much of a machine shop (hacksaw, tin snips, hand-drill) and I'm not much of a machinist.

I do have a soldering iron, though.

Here is one remote tuner that would work for you. There are other manufacturers as well. You will need to check if they work at low power levels QRP/5 Watts (I didn't check!).

MFJ Enterprises Inc. http://www.mfjenterprises.com/Product.php?productid=MFJ-926B

MFJ Enterprises Inc. http://www.mfjenterprises.com/Product.php?productid=MFJ-926B MFJ-926B Automatic Antenna Tuner covers the entire HF band and will match a random wire or coax-fed antenna 1.8-30 MHz at a full 200 Watts SSB/CW. Matches impedances 6-1600 Ohms (SWR up to 32:1).

Yes most tuners bought are very efficient plus by the time you buy all new components and pay shipping for them a home brew tuner isn't much cheaper if not more expensive.

At 160 meters they can be pretty bad but then how many hams really have the real estate for a proper 160 meter dipole or vertical. At 80 meters they aren't as efficient--certainly good though-- but for the 40 to 10 meter bands they are very good.

I suppose if one runs 100 watts a tuner built with bigger coils for 300 watts would give a few more % points of efficiency but I have never checked that assumption out.

No problem Al. You are on the right path. You sound like you know how to start, many don't. I have not built a tuner in many a year, I did do one for a field day long wire a couple of years ago. It was made open for display and show and tell for field day. Parts shown here,

http://i1102.photobucket.com/albums/g453/KD0ZZ/Tuner001.jpg

More junk thru out my album. Remote control is beyond me.

How hard and expensive is it for new hams to build an antenna tuner for use at their transmitter for use with an unbalanced line?

How about a remote tuner? If I bury coax in plastic conduit out to the center of my yard to feed a dipole overhead, does it make more sense to power it off its own low voltage power line run in the conduit or to power it off DC on the coax jacket. I'm guessing it doesn't take much power to run something like a little DC motor to turn a variable capacitor.

I'd probably bury 100+ feet of coax out to the center of the yard then ladder-line from there to a wire antenna.

Again, absolutely correct. Coax is just plain "handy". Ladder-line is very often VERY "un-handy".

> Ladder line does have it's place in our hobby as it does allow many
> types of antennas to be operated efficiently on many different bands of
> frequencies where coax losses would make it's use impractical.

Yes. Exactly.

Trying to use coax with a NON-RESONANT antenna is VERY difficult.

One must use all manner of strange methods, baluns, etc. to match a NON-resonant antenna to a transmitter if you try to use coax. In fact, I don't know of any method to use coax with a NON-resonant antenna which will work over more than one band at once.

And due to the necessity of using these "strange" methods, there is usually far more loss in the coax feed-system than if one used ladder-line and a balanced impedance transformer (coupler).

VSWR on ladder-line makes almost no practical difference whatever: VSWR on coax, makes a HUGE difference. High, and even HUGE VSWR on ladder-line exhibits no noticeable loss. Moderate VSWR on coax can exhibit substantial loss.

However, using ladder-line, and a balanced-coupler allows the average ham to use a NON-resonant antenna and achieve the same, or better, efficiencies as a resonant, properly built, coax-fed antenna could exhibit.

As I have been trying to say for the past couple of days, the only real problem with non-resonant antennas vs resonant antennas is the problem of feeding them: transferring the RF from the transmitter to the antenna with minimal loss.

ALL the losses occur in the feed-system.

Any "loss" that occurs in the properly-matched antenna itself is simply radiation of the RF, which is simply useful "work".

BOTH coax, AND ladder-line have their places, and where you can use one to good effect, it may be impossible or at least impractical to use the other.

Neither hard nor expensive IFF you 1) have the design, a schematic, of a good one, and 2) obtain the parts by careful shopping on eBay and/or at hamfests. Asking local hams for parts is also an excellent idea.

I have built several very good impedance transformers (antenna couplers), ranging from very simple to somewhat complex. I have never bought a single part for any of them which were from some commercial source: all the parts were "junque". The coupler I use every day, modeled after a Collins design, cost me a total of $5.00.

The variable rotary inductor is out of a WWII military transmitter, the two capacitors were given to me by hams, the SWR bridge is from an old CB SWR meter, the switches (very high voltage and heavy-duty) are out of a WWII BC-375 tuning unit, the verniers are also out of WWII BC-375 tuning units, the cabinet is an ex-military "open" box to which I bolted pieces of aluminum panel from a junk pile. The feet are from Radio Shack, the SO-239s are from old CB radios. Etc.

Many of the old military parts can be bought from Fair Radio Sales. They still have the switches, for instance.

Furthermore, I do not have a "machine shop", and not even a drill press. All I have ever had are small hand-tools.

> How about a remote tuner?

Again, building one from parts-available it can be done inexpensively. In my case, I am using an old satellite TV antenna "mover" to turn the variable inductor in my remote antenna tuner for my vertical so I can use it on 160 meters. I got the variable inductor on eBay. It is an old military job good for several KW and has silver-plated wire on it. I got it for about $10.00 plus shipping off eBay.

> If I bury coax in plastic conduit out to the center of

> jacket.

Not the jacket alone: both the jacket and the center-conductor too. Since you are operating at QRP power levels, or even up to 100 watts, you can very easily build a "multiplexer" to multiplex DC control voltages on the same coax

you are using for the RF.

> I'm guessing it doesn't take much power to run something like a little
> DC motor to turn a variable capacitor.

True. You can even use a computer-type "stepper motor" and gear box.

> I'd probably bury 100+ feet of coax out to the center of the yard then
> ladder-line from there to a wire antenna.

How far is it from where the coax will end to the antenna?

The reason I ask is that it seems to me that matching the coax to the ladder-line might be more complex than it is worth.

I am also trying to visualize why you need to run 100 feet of coax to your antenna? Can you not install the antenna closer to where your transmitter is installed? Reducing the length of the run of coax would be a major help to achieveing greater output power and reduced attenuation of received signals, IMHO.

As I have repeatedly said, as far as ham radio is concerned, I practically live by the KISS principle: in the long run, it is considerably cheaper, money-wise.

Also, 100 feet of even RG-8 is going to exhibit substantial loss at frequencies above 14 MHz, IMHO...but I could be wrong.

At QRP power levels, we must conserve every picowatt we can.

A Tuner can be the best first timer homebrew project.
This one below I made for a whopping 1 dollar. Well maybe a little more.

The Box is the proverbial all steel painted "Bread Box" I do not even
know if they make bread boxes anymore?
Anyway I got that one at a garage/yard sale for a buck.

The insides I got at a hamfest. They were in a box of old junk that was
like 2 feet by 2 feet by 1 foot in size a whole bunch of stuff for 5 bucks.
In the junk was an awesome roller inductor. and two caps, one wide
spaced and a differential one. here is the insides.

A pair of relays and a switch to make a by pass path, amd wham bam a tuner.

I have yet to find a match that it would not make absolutely flat 160
thru 10 meters. and have even ran legal limit power through it too with
no problems.

From: Al Bonnyman
Topic: 34134 Message: 34237

Based on replies I'm seeing, my sense is that for a simple manual tuner:

• you need 2 big variable capacitors and one big variable inductor.

• These things are expensive but last almost forever

• You scrounge junk at handsets that contains this stuff

• You scavenge the parts, figure out what their values are, then design a tuner around those values.

• Extra points for an aesthetically pleasing or bizarre recycled enclosure.

Am I missing something?

Al
KM4BYJ

P.S., thanks for everyone's help.

> achieveing greater output power and reduced attenuation of received
> signals, IMHO.

The way the various trees are arranged in my backyard, however I string up dipoles between them (NE-SW, NW-SE, N-S), the mid-point is always in about the same location over my yard. That same spot is also the best spot for a vertical if I put one up some day.

My thinking is to run coax underground to there, then ladder line up to my dipole.

Ladder line from there back to my house is more efficient but much higher-profile, looks-wise -- a factor in my environment.

While I'm doing a lot on the cheap, I'm willing to spend a bit more on long-term infrastructure: plastic conduit (which I may be able to get free from friends in the fiber business), lower loss coax, good safe grounding and lightning protection. I'm spending more on my grounding and lightning arrester than my first little QRP transceiver (about $ 150).

Al
KM4BYJ

P.S., I've made a living off and on from lightning damage -- selling and consulting about specialized test equipment and optical groundwire to power utilities over the years. As a result I am both thankful for and wary of lightning!

Please note, my reply was about the box, the balun in the picture is for 20m thru 6M, made with some 10mm dia rods, for a 160m to 40m balun I use 1/2" rods, here is a view of those parts and shows the lid with gasket. It takes a few more windings when you want 160.

I buy mine at Home Depot, Lowes or Menards in the electrical department. Here is a picture

http://i1102.photobucket.com/albums/g453/KD0ZZ/NewBalun.jpg

The lid has a rubber gasket for complete protection. They also have the SS eyebolts and hardware. Be sure a put a small vent hole in the bottom or leave one 6-32 bolt out of the SO-239 for a vent.

Anybody have any suggestions for the best place to buy an enclosure for a high-power balun, similar to what Balun Designs uses?

Thanks...

That roller inductor is exactly the same as the one I use in my "daily driver".

> and two caps, one wide spaced and a
> differential one.

That cap is not a "differential" cap, Joe: it is a "split stator".

In the split-stator cap, both sections increase or decrease capacitance
together as the shaft is turned

A differential cap has two sections also, but when the shaft is turned one
section DECREASES capacitance while, simultaneously, the other section
INCREASES capacitance.

BTW, nice job on the tuner, Joe. :-)

Subject: Re: [ham-antennas] Re: Homebrew tuners Re: Conservation of Energy

A Tuner can be the best first timer homebrew project.
This one below I made for a whopping 1 dollar. Well maybe a little more.

The Box is the proverbial all steel painted "Bread Box" I do not even know
if they make bread boxes anymore?
Anyway I got that one at a garage/yard sale for a buck.

The insides I got at a hamfest. They were in a box of old junk that was like
2 feet by 2 feet by 1 foot in size a whole bunch of stuff for 5 bucks.
In the junk was an awesome roller inductor. and two caps, one wide spaced
and a differential one. here is the insides.

A pair of relays and a switch to make a by pass path, amd wham bam a tuner.

I have yet to find a match that it would not make absolutely flat 160 thru
10 meters. and have even ran legal limit power through it too with no
problems.

AL, welcome to the Ranks, i just got into it after being away too many
years, long story , busy life. Hay you are not alone, and you do not have to
spend your whole Soc Sec Check to make this happen, i bought a really good
used Tuner , but yah know many Hams do not even use them, they just use what
they got - like a mono band Dipole or inverted V cut for Band you are active
in . Or a Fan dipole which many enjoy - if you have room then put up a long
loop like i am studying on now , some will resonate on multiple bands like a
40 /20 80/40 etc . i met a fellow on the band the other day that has a wire
beam on 40 meters ! Wow what a signal, loop might be a little easier , there

are many reasonable solutions and as you ask and read , then you will formulate the best way . Keep in mind the more connections , tuners etc you put in the way they will take up efficiency , some will disagree that a tuner will enhance , but making my Xcvr happy does not mean i am pushing up all my watts into the antenna, so it is a trade sometimes - that you have to think about - the best part of this hobby is Experimenting - you will get the most satisfaction from a QSO with something you are using that you built ! 73s, and keep on going , you are on the right track, AJ W5HEH

Well, I would use a couple of these:

https://www.fairradio.com/catalog.php?mode=viewitem&item=4490

These are HUGE, have dime-sized silver contacts, and although they were made for the BC-375 100 watt (if you were lucky) output transmitter which were used in WWII bombers like the B-17, they are also rated for 30,000 feet.

They also have (almost) a screen-door spring on the detent which takes several pounds of pressure to move. They ain't gonna move on their own.

I use one of these in my coupler to add capacitance to the "Loading" capacitor.

If you "series" the switchs up, you can switch, 6, 11, 17, 23, and more taps on your inductor. although that would take a switch for every 5 taps..

-How bad are typical losses for baluns and tuners?

Is there anything, loss-wise, that I should be aware of in buying, building or using them?-

According to some, horrible, and only resonant antennas should be used. According to others, negligible, and don't worry. It may balance out between them. I have used balanced wire antennas for years, and do quite nicely, cracking pileups regularly. I heard an older Ham last week reporting that with a G5RV, that the power loss was about 95% in the wire and the tuner, saying the tuner ate up a lot, and the coax some more. He said we were getting about 5 watts out on a G5RV we had strung up for a test. I sort of disagree. I cannot see Lewis Varney going to years of trouble to make that inefficient an antenna.

Yes, a balun has some losses. You have to induce a current/voltage in the ferrite, air, or whatever you have it wound on. This heats up the ferrite/air, and some power is lost. A long run of coax with a significant mismatch eats up more power. Some of this can be countered with antenna placement, orientation, or feed line.

I just don't think the losses are that extreme. I think you will find that your signal reports will be little different from a similar dipole or resonant vertical.

It depends: on the balun and tuner. Some can be really bad. Most are
"reasonable".

> Is there anything, loss-wise, that I should be aware of in buying, building or
> using them?

For tuners, bigger components are usually better.

> I just don't think the losses are that extreme.

Again, it depends: I agree with you when the balun and/or tuner is properly
designed and built.

>I think you will find that your
> signal reports will be little different from a similar dipole or resonant
> vertical.

Well, as an example, the same tuner I use with my 55' vertical to tune it on
all bands, including WARC bands for use with my 600 watt output linear
amp, does just as well with my 250 mW output SMK-1.

Using the SMK-1 on 40 meters, I have worked up and down the entire west
coast from Idaho, and even into Texas where I worked another SMK-1

The SMK-1, for those who don't know, is a 40 meter CW transceiver which is
slightly smaller than a pack of cigarettes. Output is "around" 250 mW (that's
about 1 quarter of a watt).

I routinely use my antenna coupler with an AN/GRC-109 military
transmitter/receiver. The transmitter outputs "around" 15 watts on some
frequencies and is crystal-controlled. I've worked 35 countries with that
through my antenna coupler.

If the losses are significant, I never know it.

Topic: 34248 Message: 34250

I live on the 15th floor of a 17 floor hi-rise. I used the MFJ window mount multi-band when I first set up my station here but was never able to achieve reasonable SWR except on 20m. I then switched to a vertical end fed wire with 9:1 balun. I was unable to get any reasonable SWR until I used a pole to move it about 5 foot from the side of the building. My building is reinforced concrete so I suspect the long wire was coupling with the reinforcement in the concrete.

I also tried the MFJ artificial ground and found it did nothing more than just using 4 random length wires for counter poise.

With my current arrangement and an external antenna tuner, I am able to work 80-10m with SWR of less than 1.5 and usually 1.1.

Good luck.

Dan 9V1DB

Concrete is conductive, and may bring the RF ground reference close to your antenna.
So, you moved your antenna away from the concrete building ?
... Good Thinking.
.
NEC requires GFCI protection for receptical circuits over concrete floors, in general practice.

Rebar, embedded into Concrete is allowed as a Grounding method for my electric services.
Sitting on concrete, and making continuity traces of multiple circuits ,
making use of a ground return,
will give erroneous readings
depending on how sweaty your pants are.

I found a great tutorial about impedance matching and wanted to share.

http://www.qsl.net/va3iul/Impedance_Matching/Impedance_Matching.pdf

The take away from this document is that every antenna can be reduced to an RLC circuit in which can be matched to your transmitter in some way, this documents presents the basic tools necessary to do so.

About 20yrs ago, I wanted to built a 1/2w 6M ant... I found a prg. at
the time
that would match any Imp. with a LC network.. I used 2000 or 2500 ohms as
the load and 50 ohms as the source.. For the test, I used a piece of
hard line,
hooked to the shield, and built the small network.. The ant. analyzer
showed
it very resonate with in the 6m band..

I didn't do any tuning it was more of a proof of concept..

Here's a link to a web based LC IMP Matching network designer panel.
There are also lots of other great tools on that page..

34255. Consensus for "best" 4:1 high power current balun design?

Yahoo group: ham-antennas (2014)
Date: 2014-09-30 14:24:48 UTC
From: wa1rkt@...
Topic: 34255 Message: 34255

Just wondering if there is any kind of consensus for the "best" 4:1 legal-limit current balun design for ladder line center fed dipoles, taking into account bandwidth, efficiency, power handling capability, and choking action.

If an article exists detailing how to build such a beast, mainly the proper way to wind the coil(s) (I'm sure there is at least one proper way and more than one improper way), that would be really helpful. I have googled and found many such articles but they are all different and in some cases mutually contradictory.

I've been a ham for 50 years this July and have done lots and lots of antenna building but, oddly enough, have never built a balun from scratch.

Thanks...

Rick WA1RKT

34256. Baluns designed for certain impedance, what if impedance is vastly different?

Yahoo group: ham-antennas (2014)
Date: 2014-09-30 14:38:51 UTC
From: wa1rkt@...
Topic: 34256 Message: 34256

Most of the balun spec sheets I have seen, from Balun Designs (my favorite these days) and others, specify power handling capability in terms of being properly matched. In other words, if you're using a 4:1 balun, they expect you to connect 200 or 300 ohms on one side and 50 or 75 ohms on the other side, and usually warn that the rated power handing capability for the balun is contingent upon keeping within those limits.

Makes sense... but what if you're using a ladder-line-fed dipole as a multiband antenna with impedances that vary all over the map both in magnitude and in phase angle? You could have an impedance of 2000+j200 that gets converted to 500+j50 with the balun, and your tuner takes care of the rest. How can you know what's going on inside your balun under those conditions? Is there a design that has a reasonable chance of working correctly at the legal limit with antennas of any reasonable impedance?

When I say "multiband antenna with impedances that vary all over the map", that's not really something that's fixable by careful pruning of the antenna, taking into account the harmonic relationship of most ham bands... I do a lot of operating on CAP and MARS frequencies that are somewhat distant from any ham band and so the antenna and balun really do need to handle any reasonable frequency (yes, I'm aware of the need to avoid certain feedline lengths depending on frequency).

Thanks...

Use a balun rated for 2 to 3 KW with 100 to 500 watts usually will be sufficient for the doublet and parallel feedline. Perhaps more power but I have not tested it as My SB200 does not give me that output.

Honest vendors will stress this point.

When transmission line style baluns are referred to as "broad band",
they refer to a range of frequencies. But at any given frequency you're
supposed to have the proper impedance on the proper side of the balun.
Some seem to confuse this.

>
> Makes sense... but what if you're using a ladder-line-fed dipole as a multiband antenna with impedances that vary all over the map both in magnitude and in phase angle? Well, what's "reasonable"? 2Kohms and a like amount of reactance?

This is the problem that balanced line and balanced tuners (without any
balun at all, like a link-coupled Johnson Matchbox) win their following.
Another option is to build a big thumper balun (see below) and put
it on the transmitter side of a tuner. But that means (typically)
you have to isolate and float the tuner. (Or use a balanced design).
Some criticise this. Some criticise the balun on the output side of
the tuner, some criticise the balun at the feed point. There are lots
of critics, arent't there?

ARRL has a whole book on tuners. In there are product reviews.
You can borrow it from somebody or get it from a library. (Or search
around QST archives.)

My guess would be (for a 4:1), a Guanella current balun wound on two large cores (separate? stacked one on the other?), these cores possibly made of "Type 2" powdered iron rather than ferrite. Like T-300-2 cores. Said simply because powdered iron is more forgiving of thermal abuse. It also has lower permittivity, which reduces the winding's inductance.

This is all very unauthoratative advice, just stuff I've heard and stumbled over; I don't have enough experience to pontificate properly. Consider it ragchew rather than advice.

NO Balun will compensate for the small losses in the balun or mismatched feedline.
If the balun does not heat up then losses are less.
Best is a "S" balanced tuner at the feedline end and short coax to Rig.
For me, I dont sweat the difference of 80 watts radiated and 90 watts radiated. The station at the other end wont know any difference. I just strive to have the best transfer of power I can make.

I dont run high power, 500 watts only when needed. Running 1500 watts and losing 3 db due to underrated or mismatched equipment in the antenna system never appealed to me.
I over rate the pieces of the system and choose to use the best available.
There fore my 500 watts on a well designed and functioning antenna system usually will work as effectively as 1500 watts into lossy coax or poorly designed parallel feedline and matching components.
It is also much less expensive.

34262. High power balun, what voltage rating for wire?

Yahoo group: ham-antennas (2014)
Date: 2014-09-30 17:06:35 UTC
From: wa1rkt@...
Topic: 34262 Message: 34262

This is another of those questions I've googled and searched this forum and gotten a wide range of different answers.

This will be for a 4:1 current balun that will be used with a ladder-line-fed dipole on a range of frequencies between 1.6 and 21, some of which are well outside of any ham band, hence I have little control over the actual impedances (resistive and reactive) that the balun will see.

I would prefer to build the balun for the legal limit although in practice will rarely if ever go above 1000 watts.

What voltage rating do I need for the wire used in the balun?

I was going to buy some of this...

14 AWG Silver Teflon Wire Assortment 25 feet 19 strand
http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&item=380998672057

http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&item=380998672057

14 AWG Silver Teflon Wire Assortment 25 feet 19 strand

There are some logistical reasons why a separate balanced tuner is impractical. So, the question remains... what voltage rating do I need for the wire?

I would look at pictures of stand alone baluns and baluns on the
blank panels of high power tuners and see if some kind of extremely
special (10 kV ?) wire was used. I don't think so.
I've seen a huge number of balun entrails wound with varnished
transformer wire, I don't think that kind of balun explode when you hit
them with 200 Watts, or whatever.

A balun is not going to bring your antenna to any kind of impedance on any frequency that it can be used anywhere but where it resonates. There is no such thing as a broadband balun. Why people keep telling you to buy or build an antenna tuner. You can't just have a line, slap a balun in it, and expect it to operate over 1.8 to 15 MHz. It just won't. Your radio won't like it one bit, no way, no how. The reason for a balun is to transform an unbalanced load to a balanced one. The impedance can still be astronomic, you are just transforming the impedance so a matcher can handle it. If a tuner is out of the question, then you are h0sed.

Gud luck on the Freebands.

Good afternoon, Alex.

It's not that I can't use a tuner... I have a half dozen or more LDG autotuners of different power levels up to 1000 watts... but I can not bring the ladder line into the shack. Can't be done. No way no how. All I can do is keep the length of coax between balun and tuner as short as practical and let the tuners handle the, as you say, sometimes astronomical impedances. LDG autotuners do a mighty fine job of handling that, by the way.

From: philrb1@...
Topic: 34272 Message: 34272

I'd like to use a high power torroid to wind a low power balun (100 w or less). The reason is to simplify the winding process...I tend to always bunch up the wires on the smaller torroids and the larger ID of a higher power torroid would make it a lot easier. What I don't know is if the physical size of the torroid plays any part in the function of the balun except for power. I need to wind a 1:1, a 4:1 and a 9:1 balun.

Any ideas, comments, or links would be appreciated.

What are the numbers on the antenna analyzer. Is there at least a dip in the readings?

Share some data from the analyzer and maybe it will give us some clues.

Subject: [ham-antennas] Help: I can not get my balcony antennas to resonate without hi-Swr

I am on the 8`th floor of a 10 story hi-rise and I have a75m. ham-stick and an MFJ multi-band antenna. I am using an antenna analyzer and can not get either antenna down to a reasonable SWR. I checked the coax for shorts and water and seems ok. I`ve taken emery cloth and wiped the coil on coil on the MFJ balcony antenna still no luck. I was told the balcony railing which is 30 ft. long and 6 ft. wide with steel panels would serve as a good ground plain. Also was told to ground my system to the hot water heating pipe with a good ground clamp. That I haven`t done as I am handicapped and can`t get down on the floor do to hip and leg injuries. I have a FT-897- d and the FC-30 tuner.

Any suggestions would be greatfully appreciated. I use an FT-857D unit in my car and a Little Toeheel with no problems.

Ah. I see. If you use ldg tuners, they also make good affordable baluns.
Good for 100 watts. For more power I have seen some kits on ebay. An
enclosure is easy to weatherproof.
I have a ldg at-100 proii. Works great. When portable I use one of theirs.
At home I use a Heathkit sa-2040 with one built in.

Date: 2014-10-01 07:24:14 UTC
From: ham-antennas@yahoogroups.com
Topic: 12267 Message: 34278

OK FOLKS:

Here are the rules of the reflector : HAM-ANTENNAS
This file will be sent once a month automatically to remind all users.

1. Name calling (race, religion, politics, gender, etc.), is prohibited.
2. Telling someone they are ignorant (in any way, shape, or form), is prohibited.
3. Denigrating other races or minorities, or expressing POLITICAL VIEWS will earn you moderation or banning.
4. If you do it privately it is a private dispute. When/if it spills over onto the reflector, you will be moderated or banned.
5. Even coming close to these boundaries is to be avoided.
6. Banning/moderation will be used, with NO notification to the transgressor.
7. Civil chatter and Civil wordage is THE rule.
8. IF the Moderators are offended, then penalties will be applied.
9. There are two Moderators, EITHER can ban/moderate you.
10. Moderators ARE the final arbitrator of disputes, we hate bickering!
11. USE Private or Direct Emails to address your concerns to the Moderators, because public postings may likely result in penalties as above. !!!!
12. Use common sense. If you would be hurt or upset if you received what you are about to send, and you are intentionally meaning to do that, DON'T DO IT!

13. We ALL would like to enjoy discussion about HAM-ANTENNAS, nothing more.

Good morning, Albert.

A balanced coupler is an antenna tuner that is specifically designed to be used with balanced feedlines, such as the old Johnson Matchbox. Most modern antenna tuners are designed for unbalanced input, i.e. coax to coax, and handle balanced feedlines with an internal or external balun.

Rick WA1RKT <kinda wishing he hadn't sold his Johnson KW Matchbox years ago>

34281. Re: [ham-antennas] High power balun, what voltage rating for wire?

A balun will exhibit high loss when attached to a balanced load that is highly reactive or that deviates from the design impedance(s). A balanced coupler (tuner, BLT, etc) is designed to impedance match a balanced load (either purely resistive and/or highly reactive) down to unbalanced 50 Ω (or other impedance if designed that way).

Losses accumulate as temperature rise in the balun core and the more power you run the hotter the temp. As a design guide, one should try to stive for the lowest Trise, and for a 100-Watt system, I would keep the Trise under 40C depending upon the core material and for low power ops 1-10W, I would design for a Trise of less than 10C for best efficiency. Heat is loss and the less heat you have the less loss you have.

> Honest question: What is the difference between a balun and a balanced coupler.

A "balun" is a "balanced-to-unbalanced" (Bal-UN) transformer with no moviing parts.

A balanced-coupler is a, usually manually, adjusted device using coils and capacitors, either or both of which may be "variable", which "couples" an either balanced or unbalanced output from a transmitter to a balanced antenna such as a symetric dipole antenna fed with balanced line such as open-wire-line. Both "sides" of the entire antenna system are exactly equal.

True "balanced" does not exist with coax-fed antennas.

The balanced antenna system, coupler, and push-pull transmitter output stages were very common up until WWII when cheap coax became available.

> I have never heard of the latter.

That's interesting....

You might find a study of old handbooks of particular interest in this regard.

A balanced antenna coupler is, essentially, a very wide-range, manually adjustable, impedance transformer.

I have given up trying to tune the 80 meter section of my 6btv. I do want 80/75 for CQWW coming up. Any ideas ? Wire would be great, small city lot, but can not have any coax hanging down (my lawn-mowing service is already dodging the trap, and a 160 trap vertical), it might be possible to string between two trees but don't think distance is great enough. Have to run about 40' of feed line through crawl space just to get to daylight. (I don't expect to run both 80 and 75 on same lead) but prefer cw portion of band.

34287. AW: [ham-antennas] High power balun, what voltage rating for wire?

Yahoo group: ham-antennas (2014)
Date: 2014-10-01 19:31:43 UTC
From: siegfried jackstien
Topic: 34262 Message: 34287

Most tune rare either t or pi type tuner (unbalanced!) ... and if you wanna connect a balanced load then there is a balun on the output side of the tuner (not a real balanced tuner but it works)

A real balanced tuner has the balun on the input side and then a balanced (symmetrical) network towards the 2 antenna connectors

So basically a "balanced coupler" is a specific type of antenna tuner that is designed to work with a balanced source and load. Whereas other tuners generally operate unbal to unbal or unbal to balanced with an internal balun.

Correct?

I have of course heard of tuners but never heard the reference to "balanced couplers".

No, we have unbalanced (coaxial) transmitter outputs and the balanced coupler has an unbalanced input. (But that's not stopping anybody from designing and building a balanced input to balanced output tuner). But the output of the coupler can either be balanced or unbalanced depending upon the design.

Coaxial input tuners can employ balanced outputs with the addition of a balun. Some employ different methods to achieve balanced outputs.

Most MFJ tuners have a Ruthroff 50 Ω to 200 Ω balun and the Palatar BT-1500 uses a balun on the input. Just different ways to do basically the same thing. There is much discussion about placing the balun on the output versus the balun on the input of the tuner. Let's not go there.

I'll have to dig out my loss measurements but here is my setup to measure the loss of two of my BLTs back to back. I think my total insertion loss was on the order of 0.15dB for both tuners when tuned to 4700-j200 ohms.

Yepp

Annecke made a similar matchbox (or almost similar)

But he added another tuning cap on the input side (input coupling coil and a cap on input)

Another knob to turn but a better match

Here is my friend's present day project. (W5MP) This is the kind of tuner real hams build and use. No MFJ stuff here. Mike has $1700 in it to date. Commercial roller inductor for AM broadcast stations and custom made bread slicer variables. Two Bird built in watt meters (forward and reverse). Good for 5KW AM. I don't like his baluns. He is changing them now.

34298. Caps with pulley for 3.5 inch tubular mast

Yahoo group: ham-antennas (2014)
Date: 2014-10-02 18:42:37 UTC
From: ka9p@...
Topic: 34298 Message: 34298

This is a bit of a longshot but hope springs eternal....

I'm modifying an old Wilson tt-45 to make it a shorter 3 section tower that cranks down to about 15 feeet (garage roof level, with the rotating base inside the garage).

The TT-45 has a 20 foot 4.5 inch section, and 20 ft 3.5 inch section, and a 2 inch mast that adjusts from 0 to 9 feet manually with two set bolt. I'm shortening those sections to 11 and 12 feet.

What I'm hoping to do is replace the welded cap that the 2 inch piece sits in with a cap on top of the 3.5 inch section that has a pulley - just like the 4.5 inch section, only smaller, so that all three sections are moveable with the cable, and use a fairly serious section of 3/8 inch wall 2.5 inch aluminum tubing to complete the top 9 feet of the mast.

Does anyone know if a 3.5 inch ID mast mounted cap and pulley assembly like the one on the 4.5 inch section is available commercially, or if something like a sailboat place might have something in stock or fabricate that could be modified to work?

I'm only using it to turn a hexbeam for now, but I'd like it to be rugged enough to support 8-10 square feet at 30 feet if I ever decide to go bigger.

Thanks alot.

Scott ka9p

Only because there are just 2 knobs to turn does not mean the efficiency is better ... if you have very high or very low impedance then you need a very wide range tuner with BIG parts

If the s match is better in that tuning range can just be measured if you have BOTH tuners and could measure the current in the wires (more fire in the wire means more output to antenna)

Gee. That IS a nice little tuner all right. :-)

About 30 years ago, I built a balanced antenna coupler with parts taken from an ex-military Wilcox 96A transmitter which operated at 3500 watts full-plate modulated AM.

Although it is pretty old, I'll try to post photos of it here.

It makes your BAT look small by comparison. ;-)

From: fconte@...
Topic: 34305 Message: 34305

I fellow from my radio club is selling his Mosley Classic 33 for $100 and a Yaesu 450a for $175 and was wondering if this is a good deal.
The 450a's dial doesn't track properly and needs to be repaired, is this easily fixed or would it need to be sent to Yaesu for repair?

Thanks for any advise you can provide...

8 years ago, I replaced traps and insulators on a cl33. Also new c clamps. Cost from the factory were over $600. Therefore, I guess the answer would depend on age and condition. You could compare that to a new innova tribander.

Gee. That IS a nice little tuner all right. :-)

About 30 years ago, I built a balanced antenna coupler with parts taken from

an ex-military Wilcox 96A transmitter which operated at 3500 watts
full-plate
modulated AM.

Although it is pretty old, I'll try to post photos of it here.

It makes your BAT look small by comparison. ;-)

So you're going to split hairs between an air core vs toroid tuner when the total loss for both is 0.15dB!

Let's (for the sake of argument) call the air core tuner loss 0.05dB and the toroid tuner loss 0.1dB, what's 0.05dB between friends?

True, the air core one on the right could handle 250W whereas the one on the left has been tested at only 100W, I use these at QRP levels anyway.

34313. Re: [ham-antennas] Balanced vs unbalanced

Yahoo group: ham-antennas (2014)
Date: 2014-10-03 03:38:48 UTC
From: Myron WVØH
Topic: 34262 Message: 34313
Attachments: 2 described; binary payloads are missing from this source WARC

Thanks Jim,

Yes, from the left side there is my homebrew BLT which is comprised of a 4:1/1:1 switchable balun attached to a perf board holding a T106-6 autotransformer with taps and Radio Shack binding posts. I attached the output of that BLT to the output of the second BLT made from some coilstock and an Elecraft BL2. The output of the BL2 is feeding the Elecraft DL1 dummy load and peak voltage detector. The peak detector monitors the voltage across half of the 50 Ω load and with some math one can obtain the power level. Quite accurately I might add.

Anyway, I set this up to measure the back to back loss of the two tuners when they were tuned to a high Z load. I first started out by attaching a 4.7k Ω resistor to the output of the first BLT on the left and adjusted for lowest SWR on my AAS-600. Then I did the same for the BLT on the right. I removed the resistor and hooked them together from Low Z to high Z then high Z to low Z, back to back. The picture shows one air variable removed because the tuning solution favored no capacitance for the left most BLT. To measure the loss, all I did was to measure the power out of the K2, log it. Insert the whole shebang, remeasure at the output, measure and calculated the loss. If memory serves me correctly it was around 0.15dB through both tuners from input to output.

The whole BLT is really an autotransformer circuit with ties back to the Palstar BT-1500 design with one important distinction, mine is a balanced autotransformer design, the BT-1500 is not. At one time I played with grounding the center tap but the whole unit was so well balanced, it didn't seem necessary. The smaller T106 design follows the schematic below while the BL2 one with the coilstock has input taps at turn 3 up from the center and has a center tap, mainly for mechanical stability.

34314. Re: [ham-antennas] Re: Really BIG Tuner

Yahoo group: ham-antennas (2014)
Date: 2014-10-03 06:26:49 UTC
From: L L bahr
Topic: 34311 Message: 34314

Yes, Gary, Mike W5MP is doing it right. He has been making changes as he is going along. Mike had Oren-Elliot, the capacitor manufacturer special make those 4 variables. I think they are around 300 pf each and cost him $250 each. That roller inductor I think it a Bower but I can't remember. I know it is for broadcast service. The baluns have been changed a couple times and he is again changing them once more. He is using one for 80-40 and another for the higher bands. The tuner is not made to go on 160. I loaned him my Palstar balanced tuner. You can see it on his shelf. He made studies of it and really poured the coals to it. The Palstar barely got warm. But, he has a Flex Radio among others and for some reason the Palstar left a local broadcast station through it and it caused havoc in his Flex front end. For that reason he changed the design to two variables on either side of the inductor. That stopped the BC station from getting into the Flex. However, that design is not as efficient as the one used in the Palstar. What is not shown are the multiple transmitting mica caps that get switched in to pad the variables. That way the higher bands are easier to tune plus he has verniers on the shafts. His switch to put the caps in parallel and switch across the variables is semi home made and was originally a military switch. I think the inductor is somewhere around 18 uH. The whole project has been going on for 6 months. One thing is certain, there is no perfect tuner. To do one thing you give up something else. I guess a lot has to do with how you plan to use it. If a guy was going to build a tuner on the cheap you could accomplish a lot for very little by not automating the project and use movable hand taps. There is a lot more flexibility that way. You really don't need a cabinet either as radiation off of a tuner is minimal.
Lee, w0vt

A very nice job indeed!

From: ka9zap@...
Topic: 34323 Message: 34323

I'm looking to replace the thhn #12 wire on my 80 Meter Windom with # 12 Flex Weave covered in black.

Any advice as to its strength, compaired to the thhn #12 and where to get the best price is greatly appreciated.

Looking on ebay as well the pricing is better on some sellers question can they be trusted?

Regards
Art

Ebat can be a crapshoot at times, though I have never had a problem buying from there.

Why not just buy it from The Wireman?

I agree Geoff. I am less than 200 mi from Wireman. Get everything worst case 2 days later. Been buying wire and coax there over fifteen years, trouble-free. Sometimes I can get a bit better price elsewhere, but the hassle factor is not worth it. Silver plated PL 259 etc from Max-Gain usually at hamfest if they have a space. Stone Mountain hamfest coming up. Time to go stock up.

Yeah, I agree with the MaxGain for connectors. I don't think I have seen any silver/teflon connectors for any cheaper of a price than what they have. I'm about to put in a fiberglass order with them and will be adding some connectors to the list as well.

On Max-Gain, all i can say is WOW when i soldered my Coax it flows so well, never seen anything like them since when i was a teen in the 60s ,we did not see this . I ordered them online , phoned them, they were very helpful . I just hope the tolerances on all these different connections fit together well so we do not have intermittent issues . So far so good with my TS930. On Wire , i got some Teflon wire from Ebay seems like good quality so far , i wound a Balun with it . I do see some Free Shipping deals that i am considering for a full size 80 meter Loop i am planning to build to before winter sets in . Had a Qso with a Fellow Ham who told me he used 16awg or so Dog wire from the Farm store a 500 ft roll is cheap and he added 68ft of 14GA and His signal is strong , he likes it , tunes 160,80,40 + more bands , uses a Tuner when needed . I am tempted to try this . He is running an amp about 800 watts + by the way. or he Feeds it with 450ohm 41ft of line from Wireman . to his tuner . 73s, AJ W5HEH

I have never noticed a practical difference.

Whatever you call it, it couples the transmitter to the line/antenna, and you tune it to achieve a match.

So call it whatever floats your boat.

From: wa1rkt@...
Topic: 34331 Message: 34331

Just wondering if a 2 wavelength horizontal loop for 160 will be a significantly better performer on 160, 80, and 40 than a 1 wavelength horizontal loop for 160.

Elevation above ground will be 50 feet in both cases.

Doing the 2-wl loop will be a lot more work, probably 4x or 6x the work or more, and most importantly I'm pretty sure I can't do it in one day's rental of a $300/day cherry picker. So unless I'm really going to see a difference I'll probably stick with the 1-wl.

Just wondering if any of you have done a real-world side-by-side comparison of a 1wl vs 2wl loop at the same elevation.

Thanks...

Hi Rick.

I have done a lot with large loops. They work but with a lot of conditions.. You did not indicate what your purpose was DX or general. Here is a little excerpt from some of my modelling and personal tests.

Conditions: Square 1 wl loop, height constant -10 feet so at 50 feet average height will be +/- 45 feet.
#14 AWG copperweld with lots of tension. It took a comealong to get just 10 feet of sag in the middle of the 546 leg.the sag was 15 feet on first try. Finally telephone guy wire and turnbuckles to achieve the 10 feet.

I did not do a 2 wl loop but would expect to have to have centenary lines from taller poles or more poles to maintain the average height.

OK Model results then my experience.

1 wl 546 feet on a side 45 feet height.

160 meters 4 major lobes with max energy at 37.5 degrees elevation and 7.9 dBi Deep vertical null
80 meters 4 major lobes longitudinally 22 degrees off axis at 30 degrees elevation 9.11 dBi very little side lobes
40 meters Many lobes omni at 24 degrees elevation very deep nulls 8.36 dBi

This one I built. It worked for DX on all bands, but was bad for anything out of the ground wave area getting better until 1000 to 1500 miles out then good signal reports. on 160, 80 and 40 With this condition. The pattern on all bands above the design, that is 80 and 40 suffered terrible nulls and caused either no copy against other antennas or QSB was dominate. But a much smaller 4 square would beat it on very long haul signals.

2 wl 1092 on a side at 45 feet height

Only modeling results to offer.

160 8 major lobes omni deep nulls at 32 degrees elevation 9.28 dBi
80 16 major lobes omni deep nulls at 24 degrees elevation 8.95 dBi
40 32 major lobes omni deep nulls at 18 degrees elevation 10.73 dBi

Hope this gives you more inputs.

Mel, K6KBE

I,ve been running a horizontal 160 mtr loop at 85 ft for the past decade. I really like it, especially on the higher bands for DX, where the takeoff angle becomes very low. Multi lobes are present , as are some nulls.

I,m expanding the loop to just over 1050 ft this week, and will pass on my observations once I get a good idea of how it performs.

There is also a Yahoo "Loops" group, you may wish to check out.

>> You did not indicate what your purpose was DX or general.

Good evening, Mel.

Not tremendously interested in DX on the low bands, it's just not my main focus. Main objective is NVIS on 160 thru 40 (and the nearby CAP and MARS freqs). Some "easy" DX (Europe and west coast US) on 40 could be handy at times.

>> Square 1 wl loop... a comealong to get just
>> 10 feet of sag in the middle of the 546 leg.

????

The 546 (ft) leg?

One wavelength for 160 meters (1.9 MHz) should be 529 feet all the way around, right? If it's a perfect square (which is rare), each side should be about 132 feet. I wouldn't think it'd be too hard to get most of the slack out of that especially since there isn't a feedline and center insulator in the middle to weigh things down.

I have a lot of tall trees rather densely packed in my back lot, so if I had to support a side in the middle of its run, I can mostly do that. A big part of the job is going to be clearing out vegetation and tree branches up to the 50-foot level so I can run the wire without it getting tangled up in branches. That's the part of the job I don't think I can do all in one day with the $300/day cherry picker.

>> 160 meters 4 major lobes with max
>> energy at 37.5 degrees elevation
>> and 7.9 dBi Deep vertical null

Since I posted my question I found a few articles with illustrated models. Unless their authors did their models wrong, what you describe seems indicative of a 2-wavelength loop, i.e. 1058 feet all the way around for 1.9 MHz. Their models showed a 1-wl loop (529 feet around) with a nice fat lobe going straight up... just what I need.

So if NVIS is my main focus, seems like the 2-wl loop isn't going to work in any case, and a 1-wl loop for 160 isn't going to give me what I need on 80 since it'll be 2 wl on 80 with the deep vertical null (not sure, yet, what it'll give me on 40).

This morning I threw up a temporary 1-wl loop for 80, about 15-20 feet high, and used it on one of tonight's MARS nets above 40. Worked OK but not as well as I hoped. Since it's 2 wl on 40, that makes sense according to the models I've seen.

What do your models show for a 1-wl loop for 160 (529 feet around) used on 40?

Rick WA1RKT

Greg;
I like the antenna you suggested. Does the "cold" side of the twin-lead connect to the "hot" side of the twin-lead, or is it just snipped off? (at the upper level of the diagram).

On my tuner, I have 4 positions, Coax 1 Direct, Coax 2 Direct, plus a coax 1 & 2 which run through a 4:1 balun. If I do as the schemetic shows, I would be running the ladder line into a 4:1 balun, and then being able to make the 75 foot run through the crawl space to the tuner, which would again run through a 4:1 balun. Using the direct positions would bypass the the tuning portion of the tuner.

Currently, I have my Coax 1 swith in line with the 160 trap vertical, a small beam (unfixable at this time) and my 6btv. I use a switch to determine which to select. As traps, there is not reason to tune. But in bringing in the coax for the 75/80 meter it would have to go through the tuner, where we again hit a second 4:1.

Got all that? Clear as mud, right?
Dale K8TS

Topic: 34331 Message: 34339

i will share from Operators on Nets etc in the last few weeks have - one guy pushes good signal from West to East coast with 160 ft loop , yah that is right total 160ft , he swears by it hard and strongly tell others to try it and ignore the models - not super high up like 30-40' max .
Other one - 577' feeds this one with 450 ohm as well uses it 40-10 and i believe a tuner .
Another mentioned to me to search "MAYPOLE" SATERN group- Salvation Army site he has this with great signal and is Net Control on prominent late night 40 meter Net .
i have the room so i am thinking 80-160 1 WL loop square with 450 ohm feed, i do have Big Tuner if needed . just not sure of length yet , i was considering 14 AWG Hard Drawn Copper , (annealed is Soft Drawn) , 7 Strands. WireMan sells it and also on EBay some deals shipped to your door free.

Another Fellow uses the Galvanized Fence posts tops 1 7/8s 21ft each , and welded 5/8s ribs on two sides at 45Degree angle all the length to prevent too much flexing in wind , used mig wire welder , just watch out for stabilizing while welding so it is straight . i can email what he sent me if you wish, a lot of details . I am very Grateful for all the help from here and others !

Anyone can chime in to share on these- for me i am and old new Hillbilly Ham who just is enjoying all , not in a rush for WAS or DX , just making Friends to visit at Hamfests and Nets . I have Trees to run them up + will have to have some type of support in between - Copper weld is strong and less expensive but not easy to put up ?? What about its stretching properties ? I understand it should radiate FB . Rick let us know what you do , and hope to hear you on the Waves sometime,

Tnx , 73s, AJ W5HEH

You are right Sigi! Unfortunately, I have always talked about loops in the terms of length on a side. My mistake, hi. Anyway, any low loop will still generate a null in the vertical plane. So not really good for NVIS use. I use a OCF dipole design. Still more omni pattern and multi band but has more energy in the vertical plane for NVIS.

Just curious, which version are you going to be building? The single-wire/balun version or the twin-lead (original) one?

I am currently in the process of gathering all of my materials for a 7-band version (40-10). All I have left to get is my fiberglass tubing for the arms.

>> any low loop will still generate a null in the vertical plane

Good morning, Mel.

Are you sure about that? The models I have seen show a deep vertical null for a 2-wl loop but a nice fat lobe, pointing straight up, for a 1-wl loop (depending on elevation, presumably).

From: David Cole
Topic: 34345 Message: 34345

Hi,
I will be installing an RCS-4 on the side of a building today... Any suggestions on what to do with the open unused SO-239 connections? Cover them with some sort of weatherproofing, or leave open? All are covered by the box itself, and pointing downwards. Any suggestions would be helpful...

Jeffery, VK4FNRS, how does the loop work?
It is just over 1 Lambda at 7 mhz.
I have the same idea and use my ICom AH2 tuner.

Well lets see it this works. I will copy the three lower band of elevation plots in my antenna file. You are right about a high lobe on 160, but 80 and 40 have nulls in a 1 wl loop. Under K6KBE antenna files. Will do one for 2 wl next.

"The models I have seen show a deep vertical null for a 2-wl loop but a nice fat lobe, pointing straight up, for a 1-wl loop (depending on elevation, presumably)."

That is what I have seen too, both from modeling and in other discussions.

The 1-wl horizontal loop inherently has a big fat lobe going straight up (and down). When placed half a wavelength above ground, which is not so easy on 160 or even 80 meters, then the reflection from the ground causes cancellation, and in THAT unique case the lobe turns into a null going skyward. So, a 1-wavelength horizontal loop almost always makes an excellent NVIS antenna, as long as you don't use very tall trees to support it! At lower heights around 1/4-wavelength up, the ground reflection reinforces the direct wave and helps the upward-going lobe.

On the harmonics, where it is no longer a 1-wl loop, then the skyward radiation is less and the main lobes move down more towards the horizon, also developing several more unfortunate nulls in different directions.

Andy

Interesting. This fellow (K5RCD) says to absolutely use a balun and never use coax. The ARRL Antenna book recommends coax and says: "Baluns or choke coils at the feed point are not to be used. They are unnecessary. Don't let anyone talk you into using them."

Yes, antennas have absolute rights and wrongs, there is only one answer ;-)

Is that the SAME antenna on 160, then on 80, and then on 40? Or is it DIFFERENT antennas, one a 1wl loop for 160, another a 1wl loop for 80, etc.?

If the former, then the antenna is 1wl on 160, 2wl on 80, and 4wl on 40, and the plots you show are consistent with what I've seen elsewhere. But if you're modeling three different antennas each 1wl at the target frequency, then what you show is vastly different from what I've seen elsewhere. Only thing I can think of is maybe your antenna elevation is 1/2wl for 80. Even then the null wouldn't be that deep I wouldn't think.

I agree! (>> any low loop will still generate a null in the vertical plane)

I have made up a 2000-plus foot loop, a 1000-plus foot loop and they were PIGS. (I had used many, MANY methods of feeding, heights, reflectors used or not, feed point locations and methods, type and length of feed-line, polarity of the window-line and so on..!) I embraced any and all suggestion. They looked magnificant, especially the 1000-plus foot loop, as it was a five-sided antenna, on poles that were all well away from trees, in an open field.

I finally learned how to interpret what the antenna modeling software (Thanks DAVE!) was showing me. Going with this CORRECT information, could easily see that the RF was not going anyplace of interest or desire! I decided to model a 75 meter loop. It looked GOOD!

I put it up, using 248 feet of #14 THHN (covered) wire at 40 feet height, on the average. It WORKED WONDERFULLY.

I made a second one, this time at 25 feet height. It also worked very well. BOTH worked LOTS better than my mega-five-sidded loops that were erected in an open field. An antenna author (I cannot recall the name, maybe it was Cebik?) had mentioned that he would NEVER AGAIN put up a loop that was larger than a full sized 75m loop. I did not believe him at first, but now I do.

Bottom line: I am voting for a full-size 75m loop.

I will add that my two 248 foot loops are a bit too LONG, but this is OK.

>> any low loop will still generate a null in the vertical plane

Good morning, Mel.

Are you sure about that? The models I have seen show a deep vertical null for a 2-wl loop but a nice fat lobe, pointing straight up, for a 1-wl loop (depending on elevation, presumably).

Sorry, I had clipped the INCORRECT STATEMENT!

I meant to endorse this in my previous post: "The models I have seen show a deep vertical null for a 2-wl loop but a nice fat lobe, pointing straight up, for a 1-wl loop (depending on elevation, presumably)."

A 1 WL loop has a very effective lobe, pointing straight up. (Been there, did that, as they say.)

73, sorry for my earlier mis-quote!

I built a single wire version with a Balun Design 1:4 balun. Bands 20m to 10M and it is a really good antenna at 40 ft in height. It has better RX than my verticals and inverted V at 35 ft in height. I also have a 2WL 160m loop that I also use.

I have had it up in the air for a couple of years and all I can say is it was worth the build. I intentionally wanted a non directional antenna and built it based on research. I am very happy that I did. I wish I would have added a 40m band to mine.

Build it you will like it. I do not have any beam antennas to compare it to but its not a small performer even though its in a small package.

Just for the record... doing some tests this evening on 80 with the temporary 1-wl loop at about 15-20 feet and an 80-meter OCF at about 45 feet. For close-in stuff up to 200-300 miles they are about the same. Farther than that, and the OCF averages about one S-unit better.

It'll be interesting to see what happens when I get the loop up to about 50 feet.

I have not used a 2-wl loop antenna , I would imagine on 160m it would have a lower take off angle vs the 1-wl loop , seems the worst part of the antenna which in a way is bad and good is on the higher bands , there are many lobes created around the horizontal full wave loop. in some directions you will have gain and others you have minus gain with fairly good take off angles, but of course height would control that a whole lot.. I would imagine the 2-wl loop would even have more crazy lobes and nulls. I have confirmed over 100 countries on the 1-wl on loop on 40-10m minus 60m which I only like 7 confirmed and only 87 confirmed on 80m with over 100 worked. on 160m I find a lack of stations on digital modes with only like 12 countries worked so far. on 160m seems like most vertical type of antennas do a little better on take off angles, but it should be better than any 1/2 wave horizontal antenna at the same height for way out there stations.. I feed mine with 450 ohm ladder line to 4:1 Balun at the shack to keep down the mismatch loss in the feedline mostly, plus the distance to the antenna.

I would double check the solder connections inside the remote unit before install. I bought one and it had multiple issues requiring me to send it to MFJ for repair and upon return it had issues again which stemmed from cold solder joints. Once resoldered worked fine.

Good luck!!!

Hi,
I have metal caps for the SO-239 connectors, and the unit works perfectly... What I am asking is about the wisdom of covering the connectors... Are they used to allow air in to help evaporate condensate? Would putting the caps on the unused connectors make the unit too tight to get rid of condensate?

More to the point, has anyone ever put the caps on, and had an issue...

"The ARRL Antenna book recommends coax and says: "Baluns or choke coils at the feed point are not to be used. They are unnecessary. Don't let anyone talk you into using them.""

Even the ARRL books were written by hams, and most hams have their opinions, which some try to present as fact.

Feeding a balanced antenna with an unbalanced feedline having a different impedance, and insisting on no balun, seems to ME like a contradiction right off the bat.

Andy

Some people think there is magic with antennas, there isn't but the
things that effect antennas cannot always be seen.
Like a car being parked near one end of a long dipole.

A balanced antenna does not always stay that way, a fed point 1:1
balun will minimize the grief when Murphy sets on one end of your
antenna. If your antenna is short and high such disturbances are less
likely.

Until about 1970, baluns were rarely used. Of course, back in the 30's, open wire feedlines and link coupled finals provided a naturally balanced feedline. But when coax came into use after WWII, I believe that most antennas were fed unbalanced. It wasn't until RF capable ferrites were developed in the 1960s that baluns became more common. (I just pulled my 1961 Handbook off of the shelf, and there is limited discussion about baluns, and then only coil or half wave phasing line types.)

One definite advantage of a coax fed loop without a balun is having the antenna grounded to drain static buildup, especially from a big loop. How is everyone handling that on your loop antennas with baluns?

Effective air core baluns were available from B&W and Heath (B1)
before ferrite was commonly available and half of the baluns today are
made with powered iron.

From: farrerfolks@...
Topic: 34375 Message: 34375

I would like to open a discussion on basic antenna design for simple use. Like portable, camping, etc. While I do a great deal of modeling before I actually go build a antenna, I also spend a lot of time doing "what if". Example: You want a 160 dipole for camping and getting back to the 500 mile and under crowd. Now I can just cut a dipole and feed it in the middle (50%) use a antenna tuner and I am on my way, right? Let's see, at 20 feet AGL, that's 21 ohms giver or take. ATU can handle that with a little added loss, right? What if I just move the feed point towards on end to say 23%. Guess what, the frequency didn't change, the pattern is the same, but the feed point impedance is now 50 ohms. No ATU needed. So if you like a resonant antenna and don't have a ATU for camping, just move the feed point!

Also if you didn't see it between the lines, this is a OCF dipole and works pretty well on other bands. To cheat a little, I put in insulated terminal strips at the sweet spots on the bands of interest and just move the feed point as needed to achieve 50 ohm match on any band of interest, within reason of course. Just a thought to get the brain cells working. Comments?

Hi Mel

Nice idea, what are the dimensions of the antenna wire where all the insulated terminal strips are placed. I go camping and this would be a nice wire antenna to have ready to go.

Hi,

G7FEK is great and easy to build antenna for 80 m band. For other bands is not good, but for 80m is really high performer.

Hi Mel,

Do you have an image or website specific for the insulated terminal strips that you are using?

Also, in your modeling do you have the % split as a variable so you can just put in the frequency of interest and have the software determine the best split for 50 ohms? If you do, I would be interested in the file for this model (either 4nec2 or EZNEC, since 4nec2 can read EZNEC files).

Tks,
Joel - N3GSE

HI Joel,
I have used several types, from the speaker flat phenolic to navy rugged micarda type. Anything that will stand the weather for short stays. I will dig one out that I used last, navy type and post a picture.
On the program. I don't have a optimizer type. I use the old method of doing a SWR sweep and look at the sweet spot frequency and impedance and adjust the location on a trial by error to get it right. Usually I am pretty good at picking the right % on 2nd or 3rd try.
What I am putting together is a cook book for each band, 160, 80, and 40 meters for portable use. The idea is to know where to put the jumper terminal strips to allow full coverage of each band. Obviously, it takes more than one length of wire to do this. More on this in the file post later today. Cheers,
Mel, K6KBE

Thanks Mel,

So is the idea that you will connect coax to different locations on the overhead wire that correspond to the right split to get close to 50 ohms impedance for a specific band? If so, how do you connect the coax to the terminal strip? I can't visualize the hardware. Interesting idea though.

Tks,
Joel

Sorry, just finishing up the file. I use a 1:1 current choke balun with the coax split out into two leads with ring lugs on one end and a BNC female on the other end. I use 12 turns of RG 303 on a 2" type 31 core toroid using W1JR winding format. Simple. This does the coupling and isolates the uneven currents from the antenna to the feed line. No RF in the operating position..... More to follow.

VHF and UHF Antenna related items For Sale:

Mobile Antenna Mounts:

Larsen LM-MM Mag Mount
This rectangular mag mount features an extremely strong
magnet. The center of the mag mount takes an Larsen LM
type antenna (5/16 inch stud). It includes coax for $18.

Round NMO Mag Mount
Black, 4 + inches in diameter, with coax. $24

BNC Mag Mount
Has BNC connector on the mag mount so you can add the
rubber duck from your HT.
Coax has BNC connector for your HT.
It permits one to get the HT rubber duck out of the
car for better performance. $22

Trunk Lip Mount
3/8 inch 24 thread stud, with coax. $10

Round Mag Mount for "Antenna Specialists" antenna
It uses the sort of reversed PL-259 type antenna that
was used for many years by Antenna Specialists.
With coax for $10.

Round Mag Mount
has 5/16 inch threaded connection, with coax $10.

White Round Mag Mount
1/4 inch threaded connection, with coax for $10.

Astatic "Mirror Mount" or "Roof Rack Mount"
Mounts to mirror or roof rack, and takes a PL-259 on one side,
and has a 3/8 inch 24 post for the mobile whip on the other.
Used for either HF or VHF/UHF antennas.
New, still sealed in the package. $12
As above, unused, but out of package. $10

Antenna Specialists Antenna Mounting Hardware:

All of the following hardware is NEW, unused, still in their
original boxes, with original paper work.

HM-66 Gutter Clip Mount
This gutter clip takes a standard 3/8 inch 24 thread antenna.
It includes coax. It is suitable for VHF/UHF antennas, but is

not rugged enough for HF antennas. NEW $15

K-221 NMO Trunk Lip Mount
This takes any of the NMO VHF or UHF type antennas. It is a nice trunk lip mount, complete with coax. NEW $15

K-66 NMO Hole Mount
This takes any of the NMO type antennas. It is made to mount in a 3/4 inch diameter hole, and includes coax. NEW $15

M-3 Ball Mount
This is a standard, heavy duty ball, suitable for use with HF antennas, or VHF antennas requiring a 3/8 inch, 24 thread antenna. NEW $15

ASC-3D Heavy Duty Ball Mount
Extremely heavy duty, Chrome plated, for 3/8-24 antennas. NEW $28

Mobile Antenna Springs:

These mobile antenna springs appear to be new. They are the chrome plated type, and designed for light to medium duty use, i.e. use on VHF type antennas, and not for heavy duty HF use.

These are about 3 inches long. I have some that are for 1/4 inch diameter antenna mounts, some for 5/16, and some for 3/8 inch. Please let me know what size you need.

These appear to be new, or at least unused.
They are $5 each.

Dual Band 2 m / 440 MHz Mag Mount Antenna:

This antenna has a very strong mag mount. The antenna itself is a quarter wave antenna on 2 meters (unity gain), and provides a couple db gain on 440 MHz. It seems to be very rugged, and even has extra strain relief on the PL-259 coax connector. It is about 20 inches tall, including the mag mount.

This particular antenna appears to be new, unused. It is the black color (not silver). $30

Hustler UHT-1, VHF / UHF mobile antenna:

The Hustler UHT-1 is 1/4 Wave Hole Mount Antenna.
It can be cut for any frequency from 136 to 500 MHz. It is low profile, with a 3/4" hole required. Includes 15' coax and connector, and is rated to handle up to 200 Watts of power. This particular antenna is new, still sealed in its original shrink wrap package. $15

Larsen mobile antennas for NLA Mounts:

Both of these fit the Larsen NLA mounts.

Larsen NLA-150
This antenna provides about 3 db gain over a quarter wave, and is a very rugged antenna, about 4 feet long. In very good condition, it the fits Larsen NLA mounts.
Coil only $10
Coil with whip $17

Larsen NLA-UHF coil for 440 MHz
This is the coil only for NLA mounts, for use on the amateur 440 MHz band and UHF public service bands.
Good condition. $10

Cushcraft 4 element 124 WB, 2 meter beam:

The Cushcraft 124WB is a 4 element wideband boomer for 2 meters. It is the right choice for packet systems and other applications requiring a dedicated directional antenna.

124WB Specifications:
Frequency: 144-148 MHz
Elements: 4
Gain: 10.2 dBi
Front To Back Ratio: 19 dB
VSWR 2:1 Bandwidth: 4 MHz.
Power: 2000 watts PEP
Longest Element: 41 inches (1.04 m)
Turning Radius: 8.8 Ft. (2.7 m)
Boom Length: 4 Ft. (1.22 m)
Wind Surface: 0.34 sq. feet
Connector: UHF (SO239)
Weight: 3 Lbs (1.6 kg)

This one is in extremely nice shape. No corrosion.
Only $75.

Coaxial Antenna Switches:

All work fine, look fine, and use SO-239 connectors.

B & W Model 550 A Coax Switch
This model will switch up to 5 antennas, and does NOT ground unused antennas. Coax comes out the side, like spokes of a wheel. It will handle the full legal limit. $35

SCP Comm Switch SC-40-AS Coax Switch
Three position antenna switch in rectangular box. Connectors on the back. In original box. May be new. $24

Two position "Strip Line" Coax Switches:

These switches utilize metal cavity construction for max efficiency and high isolation. Isolation is better than 50 dB at 300 MHz with low insertion loss less. All are two position and are typically rated for 2500 W PEP, and good to 600 MHz.

Diawa CS-201 - $20
Opek CX-201 - $20
MFJ 1702 C - With center position that grounds both antennas,
and added lightning protection. $25

Antennas for your HT:

All rubber ducks are for 2 meters, are in good
condition, and are $10 each, unless stated otherwise.

BNC - Dual Band (2 m and 440 MHz) Telescoping antenna
provides significant gain when extended, $18

BNC - As used on most HTs, 7 inches long

BNC - Original Alinco EA0024, about 4 inches long

BNC - Original from Kenwood TH-215, about 5 inches long

BNC - "Stubby" about 4 1/2 inches long

Type F connector - 6.5 inches long

BNC Stubby for 440 MHz, 3 inches long

Threaded (as used by Motorola, etc.) stubby for 440 MHz

Not a Rubber Duck, but can be used on your HT:
Telescoping Antenna w/ BNC about 19 inches long
can be used as a quarter wave antenna on 2 m,
or on 220, or 450 MHz if telescoped shorter. $12

I also have many other accessories available such as many
different types of microphones, HTs, HF, VHF and UHF rigs,
HF and VHF/UHF antennas, HF linear amplifiers, and many
other accessories.
Just too many to list here. Please e-mail your requests.

Prices do not include shipping from Florida.

Thanks.

34388. 160-meter antenna using existing tower

Yahoo group: ham-antennas (2014)
Date: 2014-10-11 21:26:11 UTC
From: wa1rkt@...
Topic: 34388 Message: 34388

I was talking with someone in NY on 160 last night (finally got my 160-meter antenna working properly) and he described an antenna for 160-meter DX using an existing tower.

Apparently, you run some RG-8 coax up the side of your 50-60-ft tower from bottom to top, taping or tie-wrapping the coax to the tower leg as it goes up (apparently you don't want the spacing between the coax and the tower leg to vary in the wind). At the top, you bond the coax shield to the top of the tower and then extend a 120-foot horizontal wire from the coax center conductor to a convenient tree or other support. You then trim that wire for resonance. Feed the antenna at the bottom with any convenient length of RG-8 to the station... in fact you could use one continuous coax run from the station, to the bottom of the tower, to the top of the tower.

The person who described it to me sang its praises as a cheap and easy DX antenna for 160. I must say I've never heard of an antenna quite like that. It almost sounds like a sort of a bazooka antenna (see The Vertical Bazooka Antenna - Ham Radio Library http://www.iw5edi.com/ham-radio/?the-vertical-bazooka-antenna,18

The Vertical Bazooka Antenna - Ham Radio Library http://www.iw5edi.com/ham-radio/?the-vertical-bazooka-antenna,18 An article by VE3VDC LD Blake Every radio amateur should build at least one antenna to prove to themselves they can improvise in an emergency.

View on www.iw5edi.com http://www.iw5edi.com/ham-radio/?the-vertical-bazooka-antenna,18 Preview by Yahoo

... except that the bottom end of the tower is presumably grounded. Not sure how that would work. It also seems to me like you'd want to have a choke at the bottom of the tower inline with the coax going to the station, although with a "real" bazooka, the coax braid sleeve is supposed to provide some choking action.

What do you all think? Have any of you done this?

I guess the best way to describe this approach is that it is an erector set of parts that let you put it up and make it work without extra stuff. See you all next time in camp.

>> I've known guys using like this since the 70's we called them 1/4 wave slopers.

Good evening, Joe.

Yes, except that with a sloper the part about taping the coax to the tower leg or running it all the way to the bottom of the tower shouldn't matter, should it? The person who described all this to me seemed to think that was all pretty important to the antenna's performance.

A related question... assume that the horizontal wire is really horizontal (and not sloped) and that you have a 20-meter beam on top of the tower. The 160-meter antenna's horizontal wire will only be a few feet from the beam, maybe like 5 or 6 feet. Any serious interactions there I need to be concerned with?

I would lay down a few dozen radials below the tower and "shunt-feet" the whole shebang (yagi would make a nice topload for the tower ... right?!?)

I have a nice gp plan for lowbands ... only 15m for 160m or 8m for 80m needed!! ... without any loading coils or tuning thingys ... and without base insulator (so you can use a grounded tower for it)

Thanks, Sigi. I have considered that and where the tower is located is not a good place for lots of radials. Anyway, I wanted to find an answer for this specific question, then another conversation about gamma-matched towers can continue under its own topic.

73,

Rick WA1RKT

34396. AW: AW: [ham-antennas] Re: 160-meter antenna using existing tower

Yahoo group: ham-antennas (2014)
Date: 2014-10-13 03:51:50 UTC
From: siegfried jackstien
Topic: 34396 Message: 34396

Original idea is from a commercial mw station here close to my qth

http://www.waniewski.de/MW/Bremen/bremen_mw_1en.htm

for 900 kc it is 45m high but has ponly 2 toploading wires

(would mean for 160 it would be 22.5m in original desingn)

with more toploading (either longer or adding more number of wires) you can get the needed height down to about 0.1 wl

I remodelled that in mmana

And depending on what you already have as tower ... and if you also have some toploading caused by a beam for the higher bands ... then maybe you do not need tooo much wire added to get resonance on 160

Shunt fed tower can be used on 160 and 80 ... but THIS shunt fed design is clever cause it has NO tuning parts (direct 50 ohms feed ...

See picture of feeding point

http://www.waniewski.de/MW/Bremen/id261.htm

....

Yes it is a massive desin ... but scaled down for our power levels and higher frequency used it does not look tooo bad

A quarterwave for 160??? Who can make that in his garden???

But a grounded and guyed tower with 15m??? that seems easier ... right?

.....

Here principle:

Take a quarterwave

Making it shorter will lower impedance to around 10-12 ohms only ... buut with feeding a sidecage and using a grounded tower you have a folded antenna ... with the neat side effect that the impedance is 4 times higher ... result ... 50 ohms :-)

that shorter and folded antenna needs toploading to keep resonance on 160 ... even if it is 15 instead of 40m :-)

with the longer version (only 2 loading wires) it ispossible to build a dualbander (160/80)

look in file section ... folded monopole

can be scaled for any band ... a 40m antenna could be made from an old cb halfwave (5m)

and the next cb halfwave makes a quarterwave for 20 :-)

34399. MFJ 259B issue

Yahoo group: ham-antennas (2014)
Date: 2014-10-15 12:31:22 UTC
From: Keith Heimbold
Topic: 34399 Message: 34399

Recently while installing some antennas my MFJ 259B went from being marginally accurate to measuring every band and frequency at >25:1. It used to do that with 160m only and now it is every band.

I replaced the batteries with known good ones and checked the connector inside to make sure good contact was being made. I am not sure what is up but seems like the mfj curse has struck me once again. I usually stay away from their products for QA reasons but I bought this product early in my ham career and would like to figure out what is up with it.

Keith,

My 269 started experiencing erratic behavior when I wiggled the antenna connector. I found that the solder connection on the center conductor was broken free. It was a pain to get at it but when I was able to finally access the connection, I resoldered it and was fine. Your case may be the diodes in the bridge may be defective or maybe a soldering issue too.

I seem to remember some 3rd party schematics floating around the Internet so you may take a crack at fixing it yourself. If not, you will need to send it back to MFJ for repair.

Subject: [BoatAnchors] Radio Estate Sale 250+ radios NJ-NY border near the Garden State Parkway

Most quality radios are $20-$25

http://tinyurl.com/NY-Radio-Estate-Sale

Estate Sale

Starting Wednesday, October 15th, there will be a Huge sale [two floors] of over 250 vintage radios including: Battery sets... Superhets... Crystal sets... Home brews... Farm sets... Vintage Amateur station... Modern amateur station ... keys... Communication receivers... Transmitters... Parts... Tubes... Books... Horns... Speakers... Test equipment...
.... Everything priced for quick sale!

Most quality radios are $20-$25...house is sold and must be vacated.
The sale is by Appointment, day or evening:
Call the daughter - Ursula @ 203-524-4939

Note: I visited the sale early, I was invited by the daughter.
All the radios I saw were in excellent 'as-found' condition, dust free and stored inside on shelves.

The property has limited parking and 'NO' on road parking.
You must call for an appointment.

The home is located near the NY - NJ border, just off the Garden State Parkway.

~ Not all radios are shown ~

Are there pictures of these radios and could you be utilized as a stand in for purchasing anything of interest. If the pricing is correct a small finders fee plus shipping would be in order. A list of Swan radios in particular. If no photo’s are available, if the price is right, might take a chance. Please let me know, and thanks

Hi Keith,

I've also initially found some bad solder joints in my "trusty" mjf259b, also. Haven't had any problems since "touching" them up.

Some time back, at a swapfest, I located some resistance "standards" in BNC connectors for a couple of $ each. They are zero, 50, and 75 ohms; the instrument is checked if problems are suspected. They are, of course, used along with a PL259 to BNC adapter.

I still have a problem with the instrument at frequencies below the 80m band because of my proximity to a local high power BCB radio transmitter. It is worst when working on vertical antennas.

73, Jimmie, K9JFK

I must be lucky, my MFJ has worked flawlessly for many years.

I bought an AIM-4170 and it's nice, but for quick tests I always grab the
MFJ first.

Today ,I found myself working on some Hamfest pickings from a recent trip to Belton. My MFJ 259 worked flawlessly as usual. I believe I bought this precision instrument in the mid 90;s in Arlington,Tx at HamCom. I bought the works .....the cover , the attachments to use as a grid dip meter ,and a set of Nicads and a charger. The durn Nicads began to not take a full charge last year. I insp the batt compartment and found everything OK except two weak batteries . I went ahead and installed a full set. Could it be that mine doesn't work either but I don't know enough to know it ? Maybe I need a radio check ! Chuck Wq5B

Question, Chuck, have you ever used the dip oscillator attachment?

If so, did it work in the UHF band?

Thanks,

Stan

Thanks Mel and everyone. I have had questionable luck with mfj products along with Heil products. They are two brands I avoid but I did buy this antenna analyzer and it has served me well for about three years before it crapped out.

Two headsets, hand mic, footswitch and hand trigger all broke within two and half years ownership. All but one was new Heil products from HRO. I have completely given up on Heil. I still buy mfj because they have some products that have been pretty good for me and they are fair priced for most part.

My plan is to troubleshoot and repair the antenna analyzer. I have a super modest QTH now and I don't want to spend much more on this station.

Keith,When my 259 connector broke, I replaced the wire to the connector with a piece of de-soldering copper ribbon, the 1/16th size. Made a flexible and solid connection.
Mel, K6KBE

From: rwhitetexas@...
Topic: 34399 Message: 34418

I just had a problem with my MFJ analyzer. Instead of the wire connection from the pcb to the connector problem, the female pin of the UHF connector on the analyzer had little gripping force and would cause erratic readings. I replaced the connector with a new one and now everything functions correctly.

Topic: 34399 Message: 34419

My suggestions on the MFJ-259B are these:

(1) Try a dummy load, or anything close to it. If readings are good, even when wiggling everything, then the >25:1 SWR you had on every band is probably not in the analyzer. If reading is not good, then go looking for loose connections inside. Start with the RF connector; that's the most suspect.

(2) It can't hurt to touch up every solder connection. If you suspect flaky behavior in an otherwise good performing instrument from MFJ, I would do that. Most of MFJ's problems are said to be caused by cold solder joints and connections they forgot(!) to solder.

Trying to debug a problem when all you have to test it on is an antenna, is a bad idea. You never know if it's the antenna being normal, the antenna being wonky, bad feedline, or the meter. Find someone with a dummy load or get one yourself. My toolbox has an old Ethernet 10base2 a.k.a. "thinwire" dummy load, and a 75 ohm TV coax dummy load. Cheap stuff. In a pinch, just stick a low value resistor on the MFJ.

I guess you might also check that the MFJ's oscillator is oscillating right. If it's gone AWOL and either not oscillating (unlikely if you get any readings) or running on a very wrong frequency, it could make the readings all wrong. The frequency shown in the LCD should show you what it is actually doing, but a sanity check can't hurt. Tune your transceiver around with the '259B running. You should be able to pick it up.

The other possibility, I suppose, is strong local interference. Got any in your neighborhood? The '259B has a broadband detector and will respond to signals that are nowhere near the ham bands.

Regards,
Andy

Thanks for all the great suggestions. It worked fine and then went bad all of a sudden.

My antennas are working great and much less than 25:1 swr according to my Acom 1000 indicator.

For shortwave i use my sark100 (now modded with bluetooth added so i can measure with laptop direct at the antenna without usb cable needed)

And for higher I use my kc901 (scalar nwa up to 3 ghz)

Static strike maybe?!? ... could it be that you connected an antenna with "charged" coax??? Or any strong transmitter close??

From: Keith Heimbold
Topic: 34399 Message: 34423

I actually wondered if that was possible. The amp and antenna analyzer are generally next to each other on my small desk area. It didn't take long from operating fine to no longer functioning.

34425. WOM

Yahoo group: ham-antennas (2014)
Date: 2014-10-18 00:21:46 UTC
From: Tom Becker
Topic: 34399 Message: 34425

FYI, you folks might appreciate this map of the HF transmit antenna farm that AT&T operated for many years in Pennsuco, Florida, west of Miami, as WOM, one of its three High Seas ship-to-shore and island telephone service stations; WOM's corresponding receive site was in Plantation, near Fort Lauderdale. https://en.wikipedia.org/wiki/AT%26T_High_Seas_Service

When it was decommissioned the transmission facility sported 38 log-periodics, rhombics and omni verticals over a half-square-mile of Everglades, each of which could handle 10kW from any of 20 or so mostly-Collins transmitters. I took a photo of the antenna map hanging on the wall, and its key, when WOM went dark in 1999.

http://rightime.com/HF/P1030367aa.JPG
http://rightime.com/HF/PennsucoList.pdf

The center of the log-periodic circle is at 25?52'29.38" -80?28'45.98". Google Earth has several overhead views from 1994 to current, when, except for the still-standing microwave (and now FM) tower, everything has been reduced to "grade-level".

Ok I went to HRO and did the impulsive thing and purchased a RigExpert AA-54 and put the MFJ259B on Craigslist for $50. The RigExpert AA-54 covers the bands I care most about and it is actually really cool and intuitive.

I appreciate all the help and perspective!!!

Hey Keith!!
If your selling the MFJ for 50 bucks, I'd like to have it. Maybe I can get it working again.

Thanks and 73,

Benton wb5twc

34429. Re: AW: [ham-antennas] MFJ 259B issue

Yahoo group: ham-antennas (2014)
Date: 2014-10-18 01:39:01 UTC
From: Myron WVØH
Topic: 34399 Message: 34429

Keith,

Welcome to the RigExpert family. I have a -269 and thought that I would miss the easy sweeping of the knob but as it turns out that I don't miss it at all. I have the AA-600 and really appreciate just about everything about it. The ability to display 5 frequencies' SWR is the bees knees. It's really handy when I tune my field doublet, I want it to tune on only one frequency at a time (because there are situations where I can get multiple SWR dips depending upon the tuning of the tuner), and the RE can quickly identify what's going on simultaneously.

When you hook it up to a computer, you can calibrate to the end of your coax and get a reading at that point, not the reading at the analyzer. (The AA-600 can calibrate on the analyzer without the computer). Btw, the hooking up to a computer was as effortless. Just download the software and go. Easy.

The AA-600 has another neat feature to send out a signal on a 2m frequency that you can program to alert you of an approaching SWR dip. Let's say you are wanting to tweek an antenna on a tower but don't have 4 hands. Simply set the AA-600 to the give a continuous SWR reading while that mode on and carry up an HT tuned to that 2m frequency you preprogrammed into the RE and listen for the rhythmic pulsing of the signal on the 2 meter HT. When the SWR is high the period is long. When a dip is approached the period of beeps increases until a steady tone is emitted telling you you are at 1:1.

The RigExpert golden rule is press the "OK" button after entering a command or expecting it to sweep, or something.

I don't want to dissuade you but there may be others sitting on the fence between the -54 and -600, the -600 gives 16 bits of resolution in the front end A/D converter. A big deal because that extra resolution allows fairly high impedances to be measured with reasonable accuracy. No other analyzer on the market can measure up to 10,000 ohms R or X, most stop at 1000 ohms.

As you can tell I love my RigExpert!

There is a RigExpert Yahoo group and we have spirited email exchanges at times but do try to help each other out. The owner of RigExpert, Denis, chimes in occasionally.

Thanks Myron! I have been using it since I got home and it is way cool!!! And I already sold the 259B to someone who wants to fix it. Plus it was on sale at HRO. I picked it up for $75 off retail price.

Win win situation all the way around.

When the SWR is high the period is long. When a dip is approached the period of beeps increases until a steady tone is emitted telling you you are at 1:1.

>
> I don't want to dissuade you but there may be others sitting on the fence between the -54 and -600, the -600 gives 16 bits of resolution in the front end A/D converter. A big deal because that extra resolution allows fairly high impedances to be measured with reasonable accuracy. No other analyzer on the market can measure up to 10,000 ohms R or X, most stop at 1000 ohms.

What a nice antenna farm ...

That would be a nice ham station :-) (multi op multi band contest location)

Interesting. I don't recall ever hearing those stations although I heard Cable and Wireless stations in Bermuda and other British islands when I was an SWL in the early 1960's.

As for the antenna farm, I'll bet some DXers would have loved to use that! I know some local DXers got to use the VOA antennas at Bethany Ohio (WLWO) when it was closed and before they were torn down. I still miss seeing those antennas when I drive up I-75.

I understand they did. AT&T allowed hams to use the WOM antennas for several weeks. At my last visit inside, two RVs were parked in the rear of the building, closest to the patch bay, surely working an impossible QRP contact - or smoking Barbados.

There was a weekend club meet, too; sort of a Field Day, except the antennas were provided. I imagine it was fun.

34434. balun

Yahoo group: ham-antennas (2014)
Date: 2014-10-19 00:29:30 UTC
From: dalecole3502@...
Topic: 34434 Message: 34434

I just purchased a Amidon HB-200 (4:1) in like new condition. It did not come with a manual. Hooking it up today, I noticed that it was not marked as to which side the balanced lline is the conductor, or does it not matter. This is my first balun in over 40 years of this grand hobby, but I don't know a thing about baluns. My only OCF dipole was factory assembled with traps. This is a home brew.
I checked the site but found no information.

Anybody got anything to share?

Hi Dale,

The PL-259 screws into the SO-239 jack and the balanced connection are the ceramic posts on the other end. It appears that there is a ground connection and you can ground it if you want but if it is at the feed point of an antenna you don't want to ground it.

I'm not sure what you mean by which side the balanced line is a conductor, so if you could say more about that.

sri wrong button.
A diagram of the antenna appears at:
http://ve3clq.blogspot.com/2011/01/w3edp-antenna.html
Does it matter which side of the balun I hook up to? The unit is unmarked.
Thanks for the info.

Your amidon is a voltae type balun?? (I am guessin yes) ... so then there is one connection to output that is dorect connected to the input hot side ...

And on the antenna sketch you see that there is a red and a black connector

Yes on a real balanced antenna and with a real balun it would not matter .. but this special antenna is not real balanced ... and your balun is a voltage type balun ... so I would guess that IT DOES MATTER where you connect what wire

I would say ... try it out ... if you can not measure what connector is hot and what is cold

No, it's a Guenalla balun. There is no "hot" or "cold" side to the balanced output. Maybe with a Ruthroff style there is may be hot or cold side but not the W2FMI style.

Output can be connected to either connection. It doesn't matter, balanced will be achieved.

I have viewed some of the other sites describing this antenna. It appears this was designed for a 'top-end' of 40 meters--Did I make a mistake in assuming (theirs that word again) that it worked on 80 meters? Still got a few hours to hang this thing as I gotta run to the Rat Shack and hope they have some PL-259. I thought I had plenty...but they all been used at one time or another, and they are less that pretty when I get done with them

It too me many years from the time I was first inteoduced to Ham Radio by my uncle (K0BXP) to it when I was a child. Mainly, Code. But almost Two Score later I gor licensed.

But I have always found an antenna farm to be a site of great beauty. (Not as much as my new XYL. But still a great beauty.)

34444. 28 Mhz 4 el beam design

Yahoo group: ham-antennas (2014)
Date: 2014-10-20 01:40:05 UTC
From: Alan
Topic: 34444 Message: 34444

I was wondering if someone might care to run the dimensions of my 4 el yagi for
28.4Mhz thru a simulation program to see if I can make any improvements to it. It is a home brew built from various bits of info I have gathered and performs reasonably well and gamma matched with an SWR under 1.2 to 1 from 28 to 28.6.
I do not have a program to look at it with nor do I have the brains to run such a program!!
needs to fit on the current boom which is 5 metres in length.
current dimensions are:
Reflector 5.335M
Radiator 4.92M
1st director 4.945M
2nd director 4.81M
spacing
refl to rad 1.58M
rad to dir 1 1.135M
dir 1 to dir 2 2.235M
I am not looking for maximum F/B ratio more for best gain.
Reason I am looking at it just now is that it is sitting on the ground while I repair the rotator which decided to strip about 30 teeth off the gear.

,
Checking ARRL Antrnna Handbook has a 6 elbeam for ten Refl=18ft,De=16' 101/2"-
Dir1=16', dir2=15'101/2",spacing R to DE=5'101/2", DE to Dir1=4'10", dir1 tro Dir2=5'6"
I hope this helps, ggod luck

Download and install mmana-gal (antenna simulation software) ... many ready to use models in it ... freeware! ... and is easy to use

If you know how to use any "paint" software (drawing a line with the mouse) ... like point, click, drag a line and then release the button ... then you also can draw antennas in mmana

34447. End fed recommendations please

Yahoo group: ham-antennas (2014)
Date: 2014-10-20 06:14:37 UTC
From: Keith Heimbold
Topic: 34447 Message: 34447

Today I built my first fan dipole and it was a big challenge to get the two bands (20m & 15m) to tune. It was a fun adventure and I almost decided to add another band but decided to hold off for another weekend. I didn't have a chance to work anyone with it because the bands seem somewhat lousy after sunset here on the west coast on the upper bands. My new RigExpert AA54 was awesome for this project.

I also just about finished my single band cobweb for 10m and now my next adventure is to figure out which end fed wire antenna to build for 80,40,and the warc bands (30,17,12).

Any suggestions out there, I am all ears. I am pretty confined on space and no commercial antennas are in my future at this property. Also nothing can be permanently mounted on the house.

Look forward to the recommendations.

Hi Keith,

Does this mean that you can have a temporary antenna? Like put it up when you operate then take it down? If so, I would consider a telescoping fishing pole. I have one that is super lightweight and take it out on my field adventures. I can have up a full-sized 40 meter doublet up in 15 minutes. I can take it down in 10 minutes.

From: Myron WVØH
Topic: 34447 Message: 34450

Oh another thought, consider a vertically oriented magnetic loop. They don't have to be up very high, like only one loop diameter above ground minimum, surely that wouldn't attract any attention. Probably the only thing that MFJ makes well are there magnetic loops. All welded construction.

I home brewed mine for portable field use. The sky's the limit. I bought a used Comet vacuum variable from Surplus Sales of Nebraska for about $240, got some Andrew 1/2" hardline with some male type N connectors laying around (I used to work in two-way radio) and mounted an L bracket to the VV cap, screwed on the Heliax. Very fun project. I'm going to try 7/8" Heliax next. My loop diameter is 4 feet and tunes 15-40m and with an additional cap, 80m.

Just brainstorming.

34451. 4 to 1 balun

Yahoo group: ham-antennas (2014)
Date: 2014-10-20 13:49:21 UTC
From: Joe
Topic: 28132 Message: 34451

Here is a question, in the 4 to 1 balun as seen below.
Say it is made for 14.175 center of the band.

Both the loop part and main feed part are electrical 1/4 waves etc.
The input end is 50 ohms as seen and output 200 ohms.

Now what happens as you slide off freq? IE: at 14.000 or 14.350 with
50 ohms still at the input end what is happening at the otyher end?

Joe,

Baluns like this are broad enough to cover the entire 20m band. They usually have 10% bandwidth maybe more if the losses are high.

The transformation will still be 200 or so ohms at the band edges.

It changes as it is not an electrical 1/4 wave of that frequency. But if you a for the centre of the band it hopefully shouldn't be out by much

Ok,
But what way is it changing? So it changes, in what way? For the
better? In other words like when it's used in the feed of a yagi,
http://www.k7mem.com/Electronic_Notebook/antennas/images/yagi_feed_balun.gif
as the impedance of the yagi natural impedance changes with frequency,
does the changes of the balun also help cancel out the changes happening
in the antenna?

I also see sometimes ther 1/2 wave delay section made from 75 ohm coax.

reason? and what happens in that situation too?

I understand what you are saying, That it shouldn't matter much. The thing is I like to "Know" what is happening no matter how small. Just so I understand it.

Just like a Diople on 28.400 Mhz that is perfectly 50 ohms because of length and height above the particular ground. at 28.350 it is still for all practical purposes still 50 ohms, AND FOR OPERATIONAL USE YOU PROBABLY WOULD NEVER KNOW THE DIFFERENCE,, but it is not really. it is now slightly capacitive reactive and different than 50 ohms also.

Thanks for all the recommendations. I have a weird property that doesn't have any center supports for a dipole bigger than for 20m length thus my building of the 2 band fan dipole. I will be using QRP most likely for the time being at this rental property. The property is pretty long but not too deep.

I recently decided to go with mobile and portable options and traded my Acom 1000 for a complete mobile setup. I will be using a KX3 at the house and as my portable. I think with low power and the KX3 there are probably many options for end fed.

Any more suggestions would be great. Hope the additional info is helpful.

When your using this type of balun to change the impedance then the length matters for frequency as the varying the length changes the impedance so it won't be perfectly 50 ohms on certain frequencies. A dipoles feed point impedance is around 75 ohms anyway not 50. If you make a transformer balun using a toroid such as ft240-43 you can get almost 200 ohms across the full HF bands. That's why these are preferable. Remember the 4:1 balun is there only to match the impedance to as close to 50ohms as possible.

A dipole in free space is yes 75 ohms or so. but close to the ground
they are far more often 50 ohms than 75. Hence the reason I stated a
dipole that is 50 ohms because of length and height above the ground.

How long is long??? ...so how much room for wire(s)

What about ocfcld (off centre fed centre loaded dipole)

Maybe with an offset fed dipole (aka windom) you can erect one antenna for many bands ... also with just a single wire

34461. AW: [ham-antennas] 4 to 1 balun

Yahoo group: ham-antennas (2014)
Date: 2014-10-20 19:50:43 UTC
From: siegfried jackstien
Topic: 28132 Message: 34461

Or folded dipole (to get to your design)

That is 300 in free air but more 200-240 above ground (or when use as fed element in a yagi)

Moving away from the nominal frequency means 2 things ... youz move away from resonant pount of the antenna AND from the resonant point of your 1:4 line transformer

In what direction it then changes on the shack end is not easy to say cause that is influenced from both things ... the balun AND the antenna

Dg9bfc

Sigi

Ps ... wink wink ... still waiting for a ball clock ... grin

A good friend was one of the operators at that station. I'd never seen the antenna layout there, but he had described it in a way that totally blew my mind. They had distinct sites to connect to, so making a multitude of Yagi's was not out of the question. (And until Fidel got hold of Cuba, that was one of his 'regulars' ---) KK4QDZ - Now with Extra Class Priv's, and a tiny KX3 to enjoy them!

34463. Re: AW: [ham-antennas] End fed recommendations please

Yahoo group: ham-antennas (2014)
Date: 2014-10-21 05:04:34 UTC
From: Keith Heimbold
Topic: 34447 Message: 34463

It is approximately 100' wide property and my current temporary 20' high mast that is temporarily affixed to the house is about 20' from the property edge so I have another 80' to the farthest edge of the property.

The situation is pretty grim here for the hobby but I have probably more to work with than some. I was thinking am inverted L or possibly an odd shaped loop maybe too but it would be pretty low. I am guessing I could put up a rectangular shaped loop of about 200' of total wire.

34464. AW: AW: [ham-antennas] End fed recommendations please

Yahoo group: ham-antennas (2014)
Date: 2014-10-21 07:47:31 UTC
From: siegfried jackstien
Topic: 34447 Message: 34464

Your loop can be rectangular ... or any other shape ... even zig zagging of one or two sides does not hurt (maybe you can have some more wire to make it resonant on 80???)

If not ... then I would erect a doublet/dipole with ladderline

Works ALL bands and does not need to be a special length ...

Just as high and as long as possible

So ... if you prefer the lower bands then as long as possible and as high as possible ... with ANY shape

I have a friend who works on topband ... with 2 times 15m only!!! (but a BIG homebrewed tuner and very wide spaced ladderline)

Ok I landed on the loop. I will put up a 200' plus loop. I will be using this with my KX3 and its internal tuner.

Thanks for the encouragement. I did build the two band fan dipole and homebrew 10m cobweb which I will also use. Antenna farm for this QTH will be complete.

Selling the gap eagle which is in my yard and taking up too much space on the patio. It is in the way and my two year old son will get hurt if it lands on him.

34467. Stacking slimjim and yagi

Yahoo group: ham-antennas (2014)
Date: 2014-10-21 13:11:29 UTC
From: soorajshenoys@...
Topic: 34467 Message: 34467

Hi all,
First of all apology if its a silly question ... But i would just like to check the possibility if it could be done... and my question is ... Is it possible to stack a slimjim antenna and a yagi antenna tuned to same frequency (approximately) on 2M band so as to avoid two dedicated feeder lines and use single feeder line instead...? Comments and suggestions are most welcome...

Thanks

Hello,

Yes, quite easily with a reactive power divider/combiner/Q-line/Q-section/whatever other name.

A quarter wave length section of 35 Ω matching 50 to 25 ohms.

http://www.dxengineering.com/search/product-line/m2-antennas-power-dividers/power-divider-frequency-coverage/144-148-mhz

>

You have a LOT more to work with than many. I've worked ops whose only option was inside their attic or a flagpole outside. Yet they did well. Actually I did pretty good for several years with only a 80m inverted vee up 20' at the center and head high at the ends. I used that on all the bands 160 through 6 (open wire feed and a tuner.) That's all I used for several years even though I have over 100 acres of land here!

Of course you won't compete with the big DX guns but if you choose your band and mode well, you can operate perfectly well with the limitations you have.

This past August, I worked Texas on 160, using that 80m inverted vee. That's 1000 miles on 160 with ten watts with a (according to the book) horrible antenna.

Of course, working the low power digital modes helps.

Sigi, I am going to challenge that. Yes, I know it's the classic answer to all antenna questions :) BUT, it should not discourage people from using what they can.

Especially if one is happy operating over shorter distances, a high antenna may underperform a lower one. For 160-80-60-40m shorter range work (under 1000 miles), a lower NVIS antenna may provide better results than something up 50 or 80 or 100 feet.

I had great fun in my novice days with a 80/40 fan dipole 18' high and with the ends bent sharply back to fit in our small lot.

I think there is too much emphasis on the big antennas that discourages many hams from even trying.

And, of course, when 15 and 10 are open, all it takes is 16 or 22' of space at 20' of height to have an excellent antenna.

73,
Ken WA8JXM

You will be pleasantly surprised with the operation of your loop, especially on the higher bands. I have used loops for more than 20 yrs. As to shape, or layout, your objective is to simply to get as much area INSIDE the loop as possible. The link below, is the best website I have found on loops and their construction. No nonsense, with straightforward instructions.

HORIZONTAL LOOP ANTENNA CONSTRUCTION http://www.k5rcd.org/hor%20loop%20instruct.htm

http://www.k5rcd.org/hor%20loop%20instruct.htm

HORIZONTAL LOOP ANTENNA CONSTRUCTION http://www.k5rcd.org/hor%20loop%20instruct.htm
HORIZONTAL LOOP ANTENNA CONSTRUCTION The Horizontal Loop, also known as the Loop Skywire Antenna, is an old but very effective design.

View on www.k5rcd.org http://www.k5rcd.org/hor%20loop%20instruct.htm
Preview by Yahoo

Good luck...and you will work lots of DX with it!

The Elecraft tuners are excellent! I wish they packaged one as a remote tuner. In my experience, the K3 internal tuner does a better job than most auto tuners on the market.

Hi,

Thanks for the reply's,
@ Myron - That link you provided gave me some idea, but one of my doubts is still uncleared the link says they are used for stacking antennas of same type (what i understood from reading) , phased ,spaced and of course the Yagi's... But my actual doubt or question i must asked was the feasibility to stack different type of antenna in my case slim jim and yagi...

@ Adrian: Agreed.. :)

@Sigi: Actually i have my very first home brewed slimjim which i never want off air and got new yagi beam both which i want to operate with single feeder (if possible) .. anyway your idea is great...

Thanks

Do you want to use the vertical OR the Yagi antenna? (or)
Do you want to split your transmit power between (and receive signals
from) the vertical and Horizontal antenna at the same time?

Hi Ron,
>Do you want to use the vertical OR the Yagi antenna? (or)

>Do you want to split your transmit power between (and receive signals
>from) the vertical and Horizontal antenna at the same time?

Yes, the concept is to stack and use both antennas at same time with single feeder line (coaxial cable)... Also both slim jim and yagi in my case are vertically polarized,,, any suggestions and comments most welcome...

Thanks

Stacking both antennas is trying to do two things half way; neither is going to do what you want. A Slim Jim is built to be a vertical low angle radiator, and does well at that. It is for hitting as many repeaters as possible in a calling area without worrying with a rotator. Mount one on the eave of your roof inside a PVC pipe, and you have one of the best repeater antennas out there, with almost 3 dB gain over a 1/4 wave, and a low angle of radiation.

A beam is for pulling in a weak signal and concentrating your transmit power into the smallest area and shooting it out to get a far away station. Many beams get as much as 10 dB of gain! Beams are for talking to a faraway station, often on SSB with meteor scatter, tropospheric ducting, or sporadic E. You can use it to talk to a faraway repeater too, if you want. When you link the two, neither gets all the power, and both have degraded performance. If you are going for distant repeaters, go vertical; if going for other stuff (ssb) go horizontal.

I would suggest feeding them separately, and using a simple switch box.

"Stacking both antennas is trying to do two things half way;"

It can be worse than that. Radiation from the two can interfere with one another and cancel in some directions. Might be worse than either antenna alone.

I don't understand why you would want to even try both antennas at the same time. What is your objective?

Andy

When I first started on HF i was using a 3-turn attic delta loop fed with my sgc239. I worked southern Argentina and New Caledonia on it. If I remember correctly, each side was only about 3 feet in length so, yes, it can be done.

My intention to choose stacking was to avoid separate dedicated feeder lines for both the antennas... not only that but also considering the fact that my beam is able to communicate with distant repeaters but not with local stations on simplex and the same can be perfectly done using my slim jim...

Considering the worst case scenario as explained i think its better to feed it with separate cables... Also i would like to know what will be effect it will put if i use a diplexer or a directional coupler ...?

Unlike Geoff I am just starting out on HF although have been on radio (free band) and a SWL for many years, at my last qth my options were very limited due to very little outside space and only wall mounting antennas and an inverted V from the VHF antenna pole on the roof however I did try a couple of EF antennas both purchased (waste of money!) and home brew at our caravan in the Northumberland hills here in the UK, my findings were that the purchased one using a 9:1 unun was problematic with tuning and caused problems with our local caravan and farm neighbors TVs and phones and the ones I built with guidance from more experienced ops using an air spaced variable capacitor and a coil worked much better with no reported interference, I once used a 30ft EF wire hanging from a tree limb vertical and tuned in the same way with the coax choked off with a toriod at about the same distance and was heard in Canada through a pileup with 5w from my little FT817nd.
I have since moved QTH again due to the xyl,s employment and now have no outside space at all being in an upper flat but have a giant of a loft space to play with, up in the loft I have my home brew 5/8 wave vhf vertical hanging from the inner ridge which does very well and after many many trials of different wire loft antennas I settled for a large vertical corner fed single wire delta loop which works from 80m (just) to 6m and does very well from 20m through to 10m, I tried it with twin feed to the tuner and with coax to a balun at the feedpoint but now use it with direct feed coax and the tuner for the best results? this works much better than the bigger horizontal rectangular wire loop I tried in the same loft space?
Even a limited antenna is better than no antenna at all.
Good Luck with the EF
Phil M6MRP

From: jonsylv@...
Topic: 34492 Message: 34492

Hi I'm new to this forum so am hoping you'll be able to advise me.

I want to drive 3 x 50ohm driven elements at the same time from my 50ohm coax feeder.

Sorry if this is a bit confusing but I hope you can make sense of it.

I have a 1/4 wave length (allowing for the velocity factor) of 75ohm coax from each of the driven elements creating 3 x coax ends each at 100ohms.

Two of these coax ends from ele 1 & ele 2 are then connected together to create a 50ohm end. Then a further 1/4 wave length is used to create a 100ohm end, this coax together with the end of the 3rd 1/4 wave length coming from the 3rd driven element is then connected to the main 50ohm feeder ..... Omg I hope you can follow that.

This should present a impedance match of 50ohm to the main feeder.

My question is will the there antennas be in phase? Since ele 1 & ele 2 two will be fed by a longer length of coax than the 3rd ele? will this be a problem? will it change the radiation pattern?

or is there a better way to feed 3 x 50 ohm ants with a single 50 ohm coax.
Thanks John G8HUY

Hi John,

Yes, having some trouble following. First off, what are the driven elements? Driven elements of a Yagi, vertical, horizontal dipole, monopole? Do you know the exact impedance of each element?

Here are some things to keep in mind. Anytime you feed more than one element regardless of impedance, there has to be consideration for phase delay or propagation delay in each connected line after the split. If one line is longer than the others, a phase change will occur. If you keep all lines equal length but space the antennas by 1/4 or 1/2 wavelength, a phase change will occur in the farfield of the radiated pattern and create peaks and nulls. You create an offset by changing line lengths to create in phase and out of phase radiation, (broadside or end fire radiation or a change in direction nonetheless).

Then it comes down to impedance matching and how those elements will interact. There are self impedance and mutual impedance considerations that complicate the actual impedances we are dealing with here.

A picture here is worth a thousand words to help you out.

I've used and do use a end fed with great success. Recently working 4w/g3zem and vk9dlx all on 100w and an endfed. The key with the endfed is getting a good earth. I use a counterpoise and peg it into the ground with approx 20m radiator. A 9:1 unun is used and then to the tuner. I've never had any RFI issues

In the ancient days, when fierce mammoths stomped about on the raised floors of ice-cold computer rooms, the character "." was the same width as "-", "|", and all others, and men drew things with them. I can still do it, but I know no one would know what I meant because some "helpful" computer would make it "pretty". I don't know how to turn that off in *your* computer from *here*, without risking jail, anyway. (It's off in mine, but this computer is Late Bronze Age, and is not part of a telephone, toaster or wristwatch.) I could also make a drawing and embed (not "attach") it in the message with uuencode, but only other cavedwellers would understand. So we will try it in words. Let A, B and C be the antennas. Lower case letters will denote junctions.

A connects to point 'a' with 1/4wave75ohm coax.
B connects to point 'b' with 1/4wave75ohm coax.
Point 'a' connects to point 'b'. They are the same point.
Point 'a' connects to point 'c' with 1/4wave75ohm coax.
C connects to point 'c' with 1/4wave75ohm coax.
Point 'c' connects to a transceiver with an unknown length of 50 ohm coax.

OK. A and B are both 1/2wave from point 'c'. C is 1/4wave from point 'c'.

Therefore, C leads A (or B) by 90 degrees. Bzzzt, not in phase.

What you haven't worried about but should: power.

If the transceiver delivers 100 W to point 'c', and each branch from point 'c' has 50ohm impedance, 50W will go on one branch (to point a/b), and

50W will go to Antenna C. So C will receive twice the juice of A or B.

>
> This should present a impedance match of 50ohm to the main feeder.

This may be so. (I agree that 1/4 wave of 75ohm line transforms 50 to 100 ohms).

> My question is will the there antennas be in phase? Since ele 1 & ele 2 two will be fed by a longer length of coax than the 3rd ele? will this be a problem? will it change the radiation pattern?

Depends how A, B, and C are arranged and what they are. Don't be shy.
Stacked Yagis? A 3 element vertical dipole array? Something else? Just
guessing, here.

Keep in mind the "gotcha", if A and B are to be 1/2 wave apart, then two
1/4 wave lines won't meet, due to the velocity factor of the lines. But
a 1/4 and a 3/4 will -- but will shift phase 180 degrees.

> or is there a better way to feed 3 x 50 ohm ants with a single 50 ohm coax.

There are many ways to skin a cat.

And what he also forget is mutual coupling between the antennas (and so no 50 ohms on feeding point)

As an example in a four square the mutual coupling can be so strong that the back element does not take power but delivers backwards power to the feeding network (and impedance becomes negative)

> time. What is your objective?

"He probably wants to be able to use only one feedline."

Well, yes ... but why does he want to drive both antennas simultaneously?
Why want BOTH non-directional and directional patterns at the same time?
What does that accomplish for him?

Many people use a Yagi to reject signals from other directions, but clearly
that can't be the case here. Others use a Yagi to get increased gain and
better signal penetration in one particular direction, but by combining
antennas, he will lose at least half his power right off the bat.

It seems to me that his objectives might be rather confused.

Perhaps he owns these two antennas already, and all he wants to do is make
use of them both and not have one of them unused, as if it would wear out
if it doesn't get used.

Andy

"What about a diplexer and keeping the antennas separated?"

Diplexer means different frequencies, but I believe he said they are both for the same frequencies.

Oh, I completely agree!

Maybe he will chime in here to explain. Personally, I think it is a bad idea.

Then the only motive I can see is trying to generate a circularly-polarized signal, which of course will not work with this schema. If you want to generate a signal with both vertical and horizontal polarization look at some of the designs used in satellite communications. In most cases these require a phasing network so that the horizontal signal is out of phase with the vertical to reduce interference.

I'm thinking that he has two 2m antennas that he wants to feed with just
one feedline and be able to use whichever one he wants whenever he wants,
not both simultaneously....

"Then the only motive I can see is trying to generate a circularly-polarized signal,"

Both antennas are vertically polarized.

"... be able to use whichever one he wants whenever he wants, not both simultaneously...."

He said he wants (wanted) to use both simultaneously.

In reality, he probably doesn't need to, but it would require another feedline, or more equipment (i.e., a coaxial relay).

In his last reply, I think he explained that he wants to get the best of both worlds ... both an omnidirectional signal (for local coverage) and the Yagi's gain (for more distant stations), at the same time without having to switch anything.

'soorajshenoys', you might consider something like a collinear antenna array, which is non-directional (in the horizontal plane) and has some gain at the same time, in all directions.

Thanks guys .... I now know it wont work as it is thanks to your replies.

I have created a ENEC design that shows a very good gain using just five horizontal 1/2 wave elements positioned almost one above the other. I do a lot of camping in my RV and need a simple but useful antenna for both 2m and 6m.
The design as it is, requires 3 of the elements to be driven as simple dipoles.
How ever since your replies have idicated that my concerns about phasing were valid I have made changes so that a balanced harness can be constructed.
Thank you for your help. I will shortly be carrying out some field trials and then once proven plan to release the design via the RSGB.

Thanks John.
I have used the doublet ant on both 80 and 40. I now use the 88 ft doublet but as an inverted "L" per another Cebik epistle. Apex at 45 foot fed with 300 ohm parallel line. Works well 80 to 20 but not 17 to 10. Need a 66 or 44 foot to work 40 to 10.
I have read most of Cebiks writings. Great source of antenna knowledge.

I., happy to see that my link to Mr Cebik,s is available to the US member.s

In addition, here is a link to an article about the lowly doublet, in the July 2001 issue of the Bexar Wire, the official newsletter from the San Antonio radio club. I hope the club does not mind me sharing this excellent newsletter with the group.

I post it because it is interesting reading, especially about the late Mr Louis Varney,s secondary thoughts on his G5RV design.I suspect not many amateurs know about this. The article begins on page 2 of the Bexar Wire link, and Mr Varney,s thoughts are the top of page 3.

The Comet is $169.

A CN-101 (HF thru 150) and CN-103M (2m/70cm) would be $180 total.

If the dual band is a separate rig, I prefer separate meters,

Buying two Daiwa meters would cost a bit to a lot more than the single twin meter. What would be your reasoning for getting two?

I would only use the dual meter thingy if i would have a ts2000 or similar
rig (one rig with shortwave and vhf/uhf) ... yes then that dual thingy would
be nice ...

But I have shortwave and vhf/uhf NOT in the same rig ... and so easier
cabling and setup with 2 different meters

...

It is just my personal thought ... better 2 independent meters

And if you go to a hamfest to a dealer and ask if he makes a spezial price
if you buy 2 meters ... maybe you get them together for 150 bucks

Or try to locate a used one (has to be functional for sure)

Look for the MIRAGE MP1 and MP2. They can be found over on e-Pay
for under $100. They have detachable couplers so you don't need to route
the coax to and from the operating position.

From: jc_2aussie
Topic: 1368 Message: 34532

I am only an F call in Australia , which is a basic licence , hwoever i have found that using meters which cover multiple bands , as with radios that do the same , you tend to end up with units that are compromises.
They due to space , harmonics , rf etc are not quiet as efficient as a frequency specific unit.
 I would opt for a hf 1.8 to 30 mhz , and a dUal band 2m to 70cm

Just my preferences

34533. Six and Ten meter Antenna question

Yahoo group: ham-antennas (2014)
Date: 2014-10-28 02:44:53 UTC
From: p_chap@...
Topic: 34533 Message: 34533

Good evening everyone. With the occasional openings on six and ten and never knowing which direction, an omni directional seems a good choice for limited playtime. Anyone have experience with the Par Electronics Omni-angle units? Highly rated on eham and low price seems to be a good niche fill antenna for my needs. I am not trying for DXCC on those bands, just a little fun at a cost that does not surpass home brew by a ridiculous margin. Comments?

34534. Re: [ham-antennas] Six and Ten meter Antenna question

Not real sure of the pricing of those loops, but you might check into the Diamond CP610 vertical 6m/10m antenna. It is a 5/8th wave on 10m, and 2 5/8's on 6m, so there's a bit of gain on both frequencies.

It can be had for about $229 from various sources.

I don't own one, but I'm seriously considering one for my Yaesu FT-8900R to replace the two independent ground plane antennas that I currently have.

Good luck with it!

I have a M2 6m loop at 18' and tonight I heard FK6CP on 6m at 579 and 58 depending on mode. I built a homebrew cobweb antenna for 10m. Both work great! For DX openings I would opt for horizontally polarized antennas versus vertical but that is my opinion.

Good luck!

34536. AW: [ham-antennas] Six and Ten meter Antenna question

Yahoo group: ham-antennas (2014)
Date: 2014-10-28 09:20:29 UTC
From: siegfried jackstien
Topic: 34533 Message: 34536

Why not homebrew "something" ??

Would give double fun

The fun that you built your antenna yourself ... and the fun to be a bit proud of the results afterwards with your homebrewed antenna :-)

I would build a fanned dipole for 10 and 6 (or better 2 of them ... reason below) and then I would buy a cb antenna (a 5/8 wl would be best) ... shorten it a bit to be resonant on 10 instead of 11m ... and then I would use the vertical as a "pole for a wire vertical that is added to the 10m element (fed in parallel at the base)

That 6m element would then be built with a small coil at the base and with 5/8 wl length (should give some gain)

Now you may ask the reason why to build 2 fanned dipoles???

Ok ...

Use the fanned dipoles as radials for the vertical elements

With some relays at the base you can feed the east-west or the north-south dipole(s) ... or the vertical(s)

Omnidirectonal vertical ... or 2 dipoles in 2 directions ...

And that all for the price of a cb antenna ... plus some relays and some wire

....

What do YOU think about THAT idea?!?

Cb antenna 50 bucks ... some wire and relays ... junk box

A weekend in the garden with a friend and an antenna analyzer

Some beer and steaks ... :-)

Go figure who has more fun ... the homebrewer or the buyer of a commercial antenna

When it comes to big monster beams .. ok then homebrewing is not easy (nor is it really cheap) and you better buy such a thingy... but when it comes to simple antennas that could be easy homebrewed ... yes then I would go that way

Dg9bfc

Sigi

Ps ... if you wanna go the easy way then an inverted v for 10 and 6 would also fit your needs ... cheap and easy ... and also near omnidirectional

34538. Help with inverted L

Yahoo group: ham-antennas (2014)
Date: 2014-10-29 08:35:13 UTC
From: lilhawk236@...
Topic: 34538 Message: 34538

I am putting up an inverted L and I am not sure what to cut it for. I do know that I am trying to get it for 160m. My radials will run along the top of my fence, I will only be able to go side-to-side and not down.

Question 1: What should I cut an Inverted L to; 135' or 234'?

Question 2: Should I cut a 160m dipole and bend it at the center?

Question 3: Will it be ok to feed it with ladder line?

I have the permission of a neighbor to use one of his tress. Great neighbor

KD8DVY/Harold

34539. Re: [ham-antennas] Help with inverted L

From: Don Sanders
Topic: 34538 Message: 34539

Harold,
You can make it most any length, depends on your tuner.
Quarter wave- 135 with 2 horizontal 135 foot radials will work well in 160 but may be hard to load on 80. But make it 165 to 170 foot and it should load well on 160, 80 and 40.

Half wave dipole= will be good but you need a 150 foot support for center if one leg is vertical and one horizontal in an "L". Parallel line, 450 ohm or higher, is good feed line. Radiation will be mostly at 90 degrees NVIS if installed flat-top and more omnidirectional if inverted vee.
Most DXers use as high vertical section as possible and rest horizontal "L" of 160 + length fed at base of vertical. Requires a good ground plane. But several have reported good results with 2 or 4 elevated radials.

Another inverted "L" type is made from 1/2 inch or larger coax. It is cut to 1/4 wave, one end is shorted and has a 110 foot wire attached. This end is elevated as high verticaly and the rest horizontal. The coax feedline center goes to the shield at the bottom and the shield of feed line goes to the center of the ant coax and they go to the radials.
Same type antenna can be made with 450 ladderline instead of coax. The 10 foot wire at the end is to tune the antenna by trimming , if necessary.
Yes, it can also be fed with the ladderline.

I hope this is helpful. I use a 88 foot inverted "L" for 80 to 20 meters fed at the center (apex) with 300 ohm line.

Why the radials along the top of a fence? It will be prone to les problems with the radials on the ground and the feed point just inches above the ground and radial junction.

Radials on the ground are not resonant and ground coupling requires many radials for good operation. Two or 4 radials raised at least 1 meter above ground and resonant at the main operating freq will usually perform well., many papers have been written explaining the research into this area.

Harold,

I had an inverted L for 80m strung up with a 33 foot telescoping pole and the rest of the wire was strung over to a tree and was horizontal. While an essentially a 33 foot vertical for 80m was just good enough, the longer the center vertical part the better as the horizontal parts is just tuning and contributes very little to far field radiation. I used only two slightly elevated 34 foot radials stapled along the top of the fence along the property boundary up about 4 feet above ground.

Then I wanted it to become a dual band 80-40m inverted L and built a small trap as I was only at QRP a levels, so I built a trap out of a 500V silver mica and a T80 iron powder toroid. I placed it at the 32 foot level near the top of the pole just past the top and bout four inches into the vertical section. Since it was a trap with a 4 to 1 Xl to Xc ratio quite a bit of loading on the 80m portion and shortened (and reduced 80m BW) but made this a really compact, sweet little dual band 40/80m inverted L. You may consider doing the same for 160/80, as the trap could be made larger for 100-W and mounted on another pole or hoisted up in a tree and the wire end could be supported off in another tree.

I bet someone homebrewed these first before the commercial guys started offering them.

But has anyone one recently homebrewed one of these? The Phasing Noise eliminators. Like this one from MFJ
http://www.mfjenterprises.com/Product.php?productid=MFJ-1026

OR This one from DX engineering.
http://www.dxengineering.com/search/part-type/antenna-phasing-and-noise-cancelling/product-line/dx-engineering-ncc-1-receive-antenna-variable-phasing-controllers?autoview=SKU&sortby=Default&sortorder=Ascending

Anyone? Schematics?

Mike Murphy, WU2D, published an extensive article on noise phasers in Electric Radio Magazine in February, 2014. He included several circuits, beginning with a completely passive one, and ending up with one which included preamps for both the noise antenna and the main antenna.

He also explained exactly how they work and how to properly make them work.

In addition, he published photos of the results when used with his R-390A, showing the noise level having been dropped by at least 30 dB. The results were quite dramatic. The reading on the "S" meter of his R-390 dropped from about 42 dB to about 12 dB.

Copies of that magazine are available from Ray at www.ermag.com for a nominal fee.

I would strongly suggest that anyone who is contemplating buying or using a "noise phaser" read his article.

Properly used, noise phasers can do a good job on single sources of noise.

34546. S9V31 as a dedicated 40M antenna

Yahoo group: ham-antennas (2014)
Date: 2014-10-29 20:40:21 UTC
From: Ken Asmus
Topic: 34546 Message: 34546

I have an S9V31 vertical that I want to use only on 40M (and possibly phase a 2nd). Current configuration has it mounted about 8 feet above ground with 4 - 1/4 wave sloping radials.

The antenna appears to be resonant around 8 Mhz with a 2:1 band from 7.3 to 8.4

I read in the manual there is a kit to convert this antenna to 40M only but can not find any details on this of how to do it.

Anyone can assist on how to lower the resonant freq to about 7.1 Mhz?

Thanks and 73,
Ken VA3KA

Hello ken,
I have the same antenna that I use on 40 meters only. I run only cw
no ssb here. The antenna is about 2 feet short of being quarter wave on 40
meters. No need for a " KIT". Couple of things you can do.
1) Make coil for at the base of the antenna to finish the length.
Take some insulated wire and wrap about 2.5 feet of it on a piece of 3" or
larger pvc pipe and then trim it to match the swr. Also the more radials
you put down will also help lower the swr some.
2) You can also lengthen the wire at the top of the antenna but
this is not easily done.
Good luck and hope this helps you out. The antenna works very good
for dx. I have about 68 radials down on mine and with the coil added to the
bottom the swr is 1:1 around my operating frequency.

Hello Ken,
The simple answer is to put a small inductor between the feed line from the vertical to the feed point and adjust the inductance with a shorting strap to lower the resonance of the antenna. It seems that from the instruction manual the radials are a little short for 40 M. The match really depends on the ground conductivity. However, I would put in a small coil, say 10 turns on a 1-1/2" dia PVC form to start. Good luck.

Stop by your local weld shop and ask for 3/32, 1/8" or so diameter TIG , or heli-arc welding filler rod. They are 36" long. A 17-7, 17-4, 15-5 or 13-8 type SS rod are the best. I have made many antenna with this materials. It might even be free for one rod. Add this to the top of you antenna and set for 33 feet overall length with a small hose clamp to hold the welding rod.
http://s1102.photobucket.com/user/KD0ZZ/media/DSC00811.jpg.html
Feed at bottom direct from coax

With your elevated radials you have enough , also make 33 ft. Slopping radial will give you a 1:1 match

Ken, check out this site which talks about using the S9v31 as a single band antenna on 40; It's actually the instruction manual and is located a few pages down in the instruction manual;

Called a Zepp. This was the antenna used on the Zeppelins in the early part of the 20th Century, just a length of ladder line with a half wave antenna hooked to one end of it and floating free. The other end of the ladder line was not terminated. You need to use a tuner/matcher, or you can use it on one band and stub feed it. I have used a double Zepp - two half wave elements on ladder line.

Get a piece of twin lead or ladder line. Determine your lowest band of operation. Cut a half wave chunk of wire for it using the formula L=468/Frequency in Mhz. Attach it to one side of the twin lead/ladder line/window line. Attach the other end of the ladder line to a matcher, the matcher to your rig.

MFJ makes these antennas <http://www.mfjenterprises.com/Product.php?productid=MFJ-6115> with the aforementioned stub, making them single band, but the way I described, with a matcher, allows them to be used on all bands above the one for which you cut it.

Greetings, i spoke to one fellow who prompted me to hook up a Top Hat to increase efficiency , but he i believe attached it lower than the top , what i am presenting is research this for an optimum Vertical since you are going to the trouble anyways- try couple of methods and then you will be very satisfied by your own results - also consider raising it to the Full 43-45' with a simple pipe mast ,like Top Fence pipe mast, Galvanized, Aluminum, or Heavy Fiberglass mast like the Military units, it is only another 12-14' , and if you already raised it some then even less , yes extend the wire . Sloped Radials use 14-18 ga wire ,(no need to waste copper i have read about OMs using 20ga), i tried 22ga no go ! I also tried a Petoway Coil , they are not fun to wind ! hihi. I also installed next to our Metal Roof covered Qth, on Rcv ok but no one heard me ! Now i am using an OCF 138 ft Dipole up about 25-30 , VERY Good Results ! on 40m Barefoot Xcvr, DX to Italy , Cuba, So America, Germany , yes some during Sunstorm about a month ago, i hear and speak with the Ozies frequently as well . My interest is not DX but Nets, and emergency fast implementation ,that is why i got the SV31' ,also for portable Fun. Do let us know the Results, for now i am planning a very large Loop , will be hard to beat the OCF performance and i have the most of the QSL cards to prove it , hihi.

Thanks to all the suggestions on lowering the resonant freq of my S9V31.

After a little experimentation I added 4 feet of wire wound on a 3" diameter form to the bottom of the antenna as suggested by a couple of posts.

This works fine. The resonant freq is now around 7.1 and the entire 40M band is now <2:1

Thanks again!

Now to add a 2nd S9V31 and phase them!!

73,
Ken VA3KA (looking for FT4TA on 40!)

Subject: [ham-antennas] Re: S9V31 as a dedicated 40M antenna

Greetings, i spoke to one fellow who prompted me to hook up a Top Hat to increase efficiency , but he i believe attached it lower than the top , what i am presenting is research this for an optimum Vertical since you are going to the trouble anyways- try couple of methods and then you will be very satisfied by your own results - also consider raising it to the Full 43-45' with a simple pipe mast ,like Top Fence pipe mast, Galvanized, Aluminum, or Heavy Fiberglass mast like the Military units, it is only another 12-14' , and if you already raised it some then even less , yes extend the wire . Sloped Radials use 14-18 ga wire ,(no need to waste copper i have read about OMs using 20ga), i tried 22ga no go ! I also tried a Petoway Coil , they are not fun to wind ! hihi. I also installed next to our Metal Roof covered Qth, on Rcv ok but no one heard me ! Now i am using an OCF 138 ft Dipole up about 25-30 , VERY Good Results ! on 40m Barefoot Xcvr, DX to Italy , Cuba, So America, Germany , yes some during Sunstorm about a month ago, i hear and speak with the Ozies frequently as well . My interest is not DX but Nets, and emergency fast implementation ,that is why i got the SV31' ,also for portable Fun. Do let us know the Results, for now i am planning a very large Loop , will be hard to beat the OCF performance and i have the most of the QSL cards to prove it , hihi.

OK FOLKS:

Here are the rules of the reflector : HAM-ANTENNAS
This file will be sent once a month automatically to remind all users.

1. Name calling (race, religion, politics, gender, etc.), is prohibited.
2. Telling someone they are ignorant (in any way, shape, or form), is prohibited.
3. Denigrating other races or minorities, or expressing POLITICAL VIEWS will earn you moderation or banning.
4. If you do it privately it is a private dispute. When/if it spills over onto the reflector, you will be moderated or banned.
5. Even coming close to these boundaries is to be avoided.
6. Banning/moderation will be used, with NO notification to the transgressor.
7. Civil chatter and Civil wordage is THE rule.
8. IF the Moderators are offended, then penalties will be applied.
9. There are two Moderators, EITHER can ban/moderate you.
10. Moderators ARE the final arbitrator of disputes, we hate bickering!
11. USE Private or Direct Emails to address your concerns to the Moderators, because public postings may likely result in penalties as above. !!!!
12. Use common sense. If you would be hurt or upset if you received what you are about to send, and you are intentionally meaning to do that, DON'T DO IT!

13. We ALL would like to enjoy discussion about HAM-ANTENNAS, nothing more.

I am thinking of buying one of these from Array Solutions. Does anyone have one of these and can give a report on how easy it is to assemble, how rugged it is and how well it performs?

From: Keith Heimbold
Topic: 34564 Message: 34564

I put up a 75' long (approx) this morning that is 20' high and 50'+ horizontal with a 4:1 balun. Tunes well with internal TS590S tuner on all bands (40 to 10), but 30m which is why I put it up. It is actually working pretty well.

Forgot the question. How do I get 30m to tune better without losing all the other bands.

Thanks & 73,

I would try to add a few feet or shorten it a few feet

Experiment a bit is the thing here ... cause you wanna use that "compromise" on all bands with tuning over coax and a 1:4 ... then it is not easy to find a length that fits all needs (also depends on metal objects close, how built, how much is vertical and how much is horizontal etc.)

Also, you didn't say if you were using a good ground or counterpoise. It will make a difference and did you measure the antenna match on 30? The numbers will tell you if you are -j or +j. That tells you which way to go on the length as Sigi suggests,

And don't forget to try it without the balun when you make changes. If the feed point is low impedance, a 4:1 balun will make it worse.

Ken,

I will try that as well. I decreased the top section and have a section that is coming down on the other end vertically and now all bands tune (80 to 6) with my external tuner. Not sure of how effective this antenna will be. I have some short radials on the ground but plan to put in a ground rod today and get some more wire going for the radials.

Thanks,

Keith

I recently made an inverted L to replace my HF9V.
Having a short garden I made a trap inverted L.
I used the standard dimensions as used in the W3DZZ trap dipole. It is working very well.
My vertical section is 40 foot and the rest horizontal. I have also put an 80 metre trap in it and extended the length to cover 160 as well.
I now have an antenna that tunes on ALL bands to 6 metres. For a time I was running it with the HF9V still up to do some comparisons and it outperforms the very good HF9V especially on 160 metres. being trapped you can tune it with an analyser. As soon as it stops raining I will upload some photos of it to the files section.
Basically the vertical section at the base is now 2 inch scaffold pole, coming down to 1 1/4 at the top.
I would recommend this antenna to anyone wanting to put out a good signal from a small plot.
One thing that is important is a good radial system. My back yard is covered in them. The don't have to be straight, you can zigzag the radials. For the radials I use very cheap fence wire. The type I use are insulated so they don't rust. This housing estate has fences round every garden and the perimeter so I have tapped into these at the lowest wire. My longest run is about 600 feet. It was noticiable the difference when I connected up to this. Cheap, easy to make, no fancy matching needed. Mayube just a home made 1:1 balun and you are away.

I have searched and searched trying to find info on this antenna. I know you would fully extend the antenna for 2 meter but do you have to lower it for 70 cm? I have a smiley antenna and you do raise and lower it for the different bands. Any help would be appreciated.

I found this on Diamond□s website:
http://www.diamond-ant.co.jp/english/amateur/antenna/ante_3hand/ante_hand1.html

H770: 144/430MHz(2m/70cm)

Length:93cm (retracted 22.3cm) 10 stages / Weight:85g
Gain:3.0dB(144MHz),5.5dB(430MHz) / Max.power rating:20W FM
Impedance:50ohms / VSWR:Less than 1.5:1 / Connector:BNC-P
Type:1/2wave radialless(144MHz),2x5/8wave radialless(430MHz),300MHz
receiving only

Seems to me that fully extended it works on both 2 mtr as well as 70cm.

I have a made a portable 40 vertical for field day, I used EMT and did a guy wire support at 20ft, a short section of smaller EMT then a old CB fiberglass whip at the top with a black band marking for CW or SSB where the smaller EMT slid into the larger. A 1" wooden dowel rod does a good job of help keeping the joint stiff . I also ran this as a full size vertical on top of my pole barn.

To all and Andy,

Does any one have a 4nec2 model file (or EZNEC) for the G7FEK antenna?
This is not a routine wire antenna to model.

any help is appreciated,
Joel - N3GSE

Thanks Ken,

I studied all G7FEK's info. In the EZNEC file I saw that in wire 6 he put in an impedance of 20 ohms of resistance and zero reactance. This is at the feedpoint. I've not seen this before. Any idea what this is?

Tks,
Joel - N3GSE

Possibly ground looses cause lower impedance since he uses only one 65 foor above ground radial. With a ground screen 1 meter wide and 30 to 40 foot long, 2 pieces crossed at center under the antenna vertical plus a couple lomg wire radials the impedance should be higher and less ground losses. This is the same with most verticals.
If you wanted to use it with out the ground screen and tuner, or only the internal tuner, the impedance can be matched better with a 1/4 wave of 75 ohm line between the base and the 50 ohm line. This will bring the 20 ohms to nearly 40 ohms. Most transmitters can live with that.

You should use 2 75 ohms in parallel ... THAT would bring 20 ohms in the 50 ohms range

Dg9bfc

Sigi

Ps 1/4 wave 75 is used to transform 100 to 50 (butternut on 20m is an example)

I think I am missing something really fundamental. I never put an impedance in at the antenna. I just run the model and it determines the impedance at the antenna.

I still do not understand why this model puts a resistive impedance in at the source.
At first I thought it was an impedance to simulate a balun to curb common mode but not just 20 ohms. It is must be there for some other reason.

Tks,
Joel - N3GSE

Ken,

I don't know about a shortened version of this antenna but thee are other really good ones for 40 and up.

A simple 69.5 foot dipole fed with 450 ohm ladder line or fed with really good low loss coax as an OCF with a 60/40 split.

What?? Shortened? Do you mean shorter than 24 to 27 feet?

Well the original idea was to have an antenna for 80 in a small garden. So when it worked he added 40. You can have 40 to 10 without 80 if desired. Just replace the 80 with a 30 meter wire and add a 20 and 17 meter wires supported by the upper wires.

If you want a 20 to 10 antenna vertical, I just finished an offcenter fed vertical that does well 20 to 10. The vertical is a 7 meter 1 inch aluminum curtain pole and at the base I have 1 inch PVC 3 meter long and a 3/4 inch 3 meter pvc in each end. They support 14 foot horizontal wires. The horizontal wires connect to the coax shield and the coax center connects to the vertical aluminum.
I use 75 ohm TV coax and the LDG 100 PRO tuner. With it mounted with the horiz wires 2 foot off ground I get fantastic reports on 15, 12 and 10. 20 works well and perhaps better when I raise it to 3 meters above ground. 17 meters is high SWR so I will add a second vertical wire for 17 and try that. More work is needed to find the best compromise lengths of the horiz wires but I'm close.

Sigi and all others,

I think I see the light. The 20 ohms inserted in the EZNEC model for the G7FEK wire #6 that goes to ground is there to simulate the ground being lossy to the tune of 20 ohms. Doing this would give a more realistic model result then if the 20 ohms were not present. If the 20 ohms were not present I think the model would be using zero ohms ground resistance which would be a perfect ground. Is the choice of 20 ohms just a guess at the ground resistance or is there more to it?

Am I correct about all this?

Tks,
Joel - N3GSE

Joel,

I believe that is the best explanation so far. (You've hit the nail on the head). But it may not matter as the accuracy of the model will be severely limited by the inability to model that piece of 450 Ω window line carrying unequal currents by virtue of unequal antenna lengths attached to it. True, the bottom two wires are shorted together but they diverge as you go up. You can't put in a TL in there because that assumes equal currents, (unequal phase progression here in this design). You can't place two wires next to each other, because that will cause erroneous results. So this may not be modeled accurately with any NEC version, a known limitation. I've tried to model adjacent, close spaced wires in the past and usually end up in frustration, at least with my version of EZNEC+ 4.something.

But all is not lost. Taking what we have learned from our past experience we can usually predict how that antenna may act. On 80, it's somewhat short and short antennas usually end up having a fairly low input Z, and if mounted low, an NVIS radiator with a reduced efficiency because of the proximity to earth and heating of associated worms. There will be radiation from all parts of that antenna without a Guanella balun reducing common mode and forcing equal currents up/down the feedline. And since there is asymmetry to the whole works, there will be lobes and nulls galore on the higher bands. We can do better with a more symmetrical antenna by saving that window line for a better purpose to feed some sort of a doublet arrangement and concentrate on getting it as high as possible.

Myron,

Yes the EZNEC model when converted to 4nec2 has problems when it is run. I am taking a shot at modifying the model and have now got it to run with no segmentation errors and no warnings.

What looks like 450 ohm ladder line I have correctly spaced as just normal antenna wire so there is no error associated with wires being too close. And the segmentation is now correct for 4nec2. There is still a problem with the average gain test and with the convergence test. I am not sure I can correct this but I am still trying.

The antenna efficiency is low (35%) and the radiation efficiency is even lower (16%). This antenna does indeed model as a vertical antenna with ground being very important. On 80M however, this space saving antenna does well with its low angle of radiation. I agree with you about other antennas so I just might not finish with my modeling mods for this antenna.

Tks,
Joel - N3GSE

Myron,

It's in Cebik's Part 4 QST Feb 2001. I am not sure if the Conv test shows there is a problem with the antenna structure or it exceeds the limitations of the NEC core. The Conv test is in the Optimizer section.

Tks,
Joel - N3GSE

Mel,

I am not an expert at this. Background is chemistry and all this stuff is for pure fun. From what I read, the convergence test runs the model at increasing number of segments. If the model is a good one, there should be little difference in the results from the runs.

I have modified the EZNEC file that G7FEK provides which I converted to a .NEC file and it runs without errors and both the AGT and convergence test look good.

Interesting that the first run before modification and with all the errors when run with 4nec2 has pretty much the same results compared to the run with my modified and error free .NEC file. For me it was a good exercise in learning.

Tks,
Joel - N3GSE

34598. Traps / Coils

Yahoo group: ham-antennas (2014)
Date: 2014-11-06 21:22:36 UTC
From: Jim Upson
Topic: 34598 Message: 34598

Hi ..... my first time posting...and a relative newbie.....I am in need of making the most efficient trap dipole possible (QRP operating). I am thinking that I'll build the following to fit into 30 foot inverted-v configuration:

A) one trapped dipole to work 20/40 meters....
B) and another trapped dipole for 17/30 meters....

So I would appreciate your input regarding what trap/coil type is the MOST efficient (lowest losses) to make....and which, if any, are not even appropriate for my multi-band trap dipoles. The one's I am aware of are:

1) wire coils/traps.....such as: Phil Salas Build your own coils <http://www.ad5x.com/images/Articles/CoilRevB.pdf> , or Unadilla pre-made traps <http://www.unadilla.com/pricelist/traps>
2) wire traps..... such as: Phil Salas 12/17 Trap Dipole <http://www.ad5x.com/images/Articles/Trap%20Dipole%201217RevA.pdf>
3) coax wound ..... either single or 2 coaxes wound together <http://9k2ra.net/wp-content/uploads/2011/12/Trap-Dipole-Antenna.pdf>
4) close wound magnet wire.....as found on Alpha-Delta DX-ee <http://www.alphadeltacom.com/pg1.html> or MFJ-17754 <http://www.mfjenterprises.com/Product.php?productid=MFJ-17754>

My GUESS is that the most efficient are in order shown above...e.g., wire coils, wire traps, coax traps, magnet wire traps....But...I have no idea....

Can you provide insight or better solutions?

Requirements: attic only (30x60)....only 18 feet off-ground....so I know DX will be compromised...but doable. I noted that the DX-ee and MFJ-17754 will fit in a manner that perfectly aligns NE/SW from Delaware....(my house front points due north). I know....I know...not the greatest scenario....hence my request for your help...what will be most efficient.

73, Jim, K3JRU

Jim -

Have you considered making a doublet? No need for lossy traps. Multi-band in ONE antenna wire. Make the two legs as long as possible, but equal in length, run a short length of coax from the back of your radio to a 1:1 or 4:1 balun, and then ladder line (450-ohm stuff works fine) to the apex of the antenna. The only requirement is that you need a tuner; either an external tuner, or one built into the radio, which most rigs have these days. I think you'd be quite pleased with the results. I've used one here at this QTH for the past four years; have managed to complete 8BWAS (eight band worked all states), and countless DX countries. Granted, my antenna is longer (88 feet) and higher (45 feet), but you'll have no problem making a lot of QSO's with one of these antennas.

Just my 2-centavos worth.

Mel,

My modifications were basically minor just to get 4nec2 to get no errors. So the comparison I referred to was for g7fek's posted file on his website converted to 4nec2 which gave errors vs. this converted file, which I modified and then got no errors.

I did not do other comparisons such as big changes in height, etc.

Tks,
Joel - N3GSE

I agree with James. The best bang for your buck will definitely be the doublet antenna. It is a simple, all band antenna, that will not break the bank.....and it works extremely well. Check out the plans on this ham universe website. Good luck.

I also agree with James. The doublet fed with 450 or 300 ohm line from a balun and coax to you transceiver is most efficient antenna. I have used them for 60 years. If your space is 60 feet long, make the antenna 60 to 70 feet long, then bend the last couple feet on each end and you wont know it is not straight.
Make the apex high in the center and drop ends to the corners of the space.
You may find a band that has trouble loading and may need a 1 to 1 balun, ugly balun or other, for that band or maybe 2.
Ypur fortunate as many dont have that much space.

Thank you all for your replies....!! I do appreciate your insight.

Actually I also was planning to put up a doublet...and then do a/b comparison with the traps....as part of my self-imposed 'training'.....I found very encouraging blogs about using Alpha-Delta DX-ee in ranch style house attics like mine....so I thought I'd try to make my own version....

> With that said....do you know if one of the 4 various coils/traps is superior to the rest?
1) wire coils/traps.....such as: Phil Salas Build your own coils
http://www.ad5x.com/images/Articles/CoilRevB.pdf , or Unadilla pre-made traps
http://www.unadilla.com/pricelist/traps
2) wire traps..... such as: Phil Salas 12/17 Trap Dipole
http://www.ad5x.com/images/Articles/Trap%20Dipole%201217RevA.pdf
3) coax wound ..... either single or 2 coaxes wound together
http://9k2ra.net/wp-content/uploads/2011/12/Trap-Dipole-Antenna.pdf

4) close wound magnet wire.....as found on Alpha-Delta DX-ee
http://www.alphadeltacom.com/pg1.html or MFJ-17754
http://www.mfjenterprises.com/Product.php?productid=MFJ-17754

> Regarding doublets....my plan was to install it as an inverted-L....e.g., with half of it either vertical or sloping, and the other half running horizontal across the peak of my roof line..18-feet above ground.....FYI...it was going to be a 44' doublet....e.g., two 22' sections from the feed-point. With it inverted L, it will mean the feed-line will run ~45-degrees away from the feed-point vs. the normal 90-degrees....OR....should I just run it horizontal?

Well...thanks again for any insight you have to either the trap/coil question and/or the doublet question.

Most hams these days don't liket traps. They are lossy, narrow band, heavy, aggravating to make, and can be expensive, to name a few. A true doublet fed with balanced line is low loss, wide band, and very efficient. The doublet begins to have directional characteristics past half wave. The only loss in the system is in the tuner, and that is minimal.

34605. Re: Traps / Coils / Cheap 80mt antenna

Yahoo group: ham-antennas (2014)
Date: 2014-11-07 09:21:56 UTC
From: jc_2aussie
Topic: 34605 Message: 34605

I used a doublet for sevral years in a very small yard 36ft x 45ft, invarious configurations, and while id did reasonably well on 80mt it was not as efficient on highr bands . The doublet was 140ft approimatly and 20 ft above ground fed with open line feeder, but no balun (this may have been the cause of the inefficiency)
I now have a 150ft loop with open line feed and a balun, i can now get the USA on 40mt band when the band opens up , .
My advice is to experiment, and see what suits your location , and needs the best.

My 2cents worth.

Jim,

Yes, do experiment. Don't let ham-lore stop you from building traps and the like. Most hams shun traps but yet swear by an end fed half wave antenna and yet they are, component wise, identical. Anytime you parallel a capacitor and inductor to create an end fed situation you have exactly the same combination of components that comprise a trap.

And contrary to popular belief the higher the trap Q the broader the SWR for the antenna.

I've had success building 20m QRP traps out of T50-6 cores and 500V silver mica caps. Your |Z|=Q*XL, meaning you get higher trap impedance (and Q) by maximizing the inductive reactance for a given resonant frequency. In my situation on 20m, that means having an inductance of around 3-4μH for a 30-40pF capacitance. But you are limited by the ability to get a high Q inductor with the core material and size. Usually the trap Q is limited by the inductor Q but in the case of the Unadilla traps it may be the other way around. I'm currently analyzing why those traps are poor performers. It could be that there is a chunk of aluminum extending through the center of the coil or the low Q capacitor formed by shoving two tubes of aluminum together with unknown dielectric cemented together with lossy epoxy, I am not sure why but they should have much higher Q than they exhibit. And that's another thing, you rally need a Q meter or impedance analyzer to know what the Q of a component is doing. Network analyzers, antenna analyzers and the like favor impedances near 50 Ω thus cannot accurately characterize high Q components, but impedance analyzers are built to provide accurate readings at impedance extremes. Lots of info on impedance analyzers on the Agilent (er, Keysight) website.

A trap can exhibit good performance if designed properly but unfortunately there are many designs out there that are not.

I have another method for making traps. First get the right ratio from the handbook then I make the trap as a series tank and one end to a analyzer the other end to 50 ohms. When the trap is adjusted properly, the analyzer with be 1:1 on frequency. Simple. On the HF bands, I make a series network from the analyzer center terminal to the coil to the cap to a 2 w 50 ohm carbon resistor to shell on the analyzer.

I put up this antenna today and so far I don't know how it compares to my inverted L which is now the radials for the antenna. It is not tuned well on 40m so I will have to figure that out. So far it is spot on for 30,20, 17, and 10 and tunable with my internal ts590s internal tuner on 80, 40 and 15. I used 28' of ladderline.

34611. Question for he group

Yahoo group: ham-antennas (2014)
Date: 2014-11-07 21:15:42 UTC
From: John Murphy
Topic: 34611 Message: 34611

I am not new here, having been on this group for about 1 ½ years now, and I have gained some good knowledge. A post did catch my eye, the thread about the cheap & easy 80 meter antenna. Currently I have this up: http://www.hy-gain.com/Product.php?productid=AV-18VS . Yes I know it is not perfect, but HOA□s being what they are, I submitted a request and got permission. Anything is better than nothing to get on the air. The thread about the cheap and easy 80 meter antenna got me to thinking about possibly changing my antenna situation. Here is my idea:

I would like to take about 60 feet of a thin (invisible) wire from the top of my antenna and run it to the front part of my home. The wire would be horizontal, and, I think, that would give me better propagation on 80, 60, and 40 meters. The antenna right now is ground mounted and works ok on 20 & up, but I would like better performance on the three lower bands as well.

My radio is a Kenwood TS-2000 with internal tuner, so currently I have the shorting clip on the coil of the antenna set at the 20 meter position, and it does tune all bands but I was hoping with my idea of getting better performance on the three lower bands.

Any suggestions would be considered and I was hoping someone could give guidance on this idea (at least before I go climbing on the roof to do something that might not be feasible).

How about a Zepp through a more beefy tuner? I use a double Zepp, or Doublet that, rather than wearing myself out, bought from MFJ (MFJ-1777 http://www.mfjenterprises.com/Product.php?productid=MFJ-1777). The Zepp antenna is sort of the original end fed, and can be tuned for any band up from the fundamental.

I am not new here, having been on this group for about 1 ½ years now, and I have gained some good knowledge. A post did catch my eye, the thread about the cheap & easy 80 meter antenna. Currently I have this up: http://www.hy-gain.com/Product.php?productid=AV-18VS . Yes I know it is not perfect, but HOA's being what they are, I submitted a request and got permission. Anything is better than nothing to get on the air. The thread about the cheap and easy 80 meter antenna got me to thinking about possibly changing my antenna situation. Here is my idea:

I would like to take about 60 feet of a thin (invisible) wire from the top of my antenna and run it to the front part of my home. The wire would be horizontal, and, I think, that would give me better propagation on 80, 60, and 40 meters. The antenna right now is ground mounted and works ok on 20 & up, but I would like better performance on the three lower bands as well.

My radio is a Kenwood TS-2000 with internal tuner, so currently I have the shorting clip on the coil of the antenna set at the 20 meter position, and it does tune all bands but I was hoping with my idea of getting better performance on the three lower bands.

Any suggestions would be considered and I was hoping someone could give guidance on this idea (at least before I go climbing on the roof to do something that might not be feasible).

Sounds like a good plan to me. Of course since you are feeding against ground, the better ground system or counterpoise you have, the better. Hopefully your HOA isn't concerned about invisible buried wires, is it?

As for your antenna not being "perfect", there is no such thing as a perfect antenna. Even a 4 element 40 or 80m beam isn't a perfect antenna. All antennas are compromises of one sort or another.

73,
Ken WA8JXM

Yes, back eons ago when we lived in an apartment, I had about 200' of 28ga wire strung out the window :)

John,
 What you propose can be considered an end fed Marconi. Does not need to be resonant with the coil at the bottom to make up the difference. I regularly use a trailer tongue mounted 33' vertical with a coil and when the situation presents itself, add random wire to the top. In the trailer park everyone sees the vertical but not the extra #18 gray bare nickle plated wire. Sneaky but works MUCH better on the low bands. Give it a try.

  How about a Zepp through a more beefy tuner? I use a double Zepp, or Doublet that, rather than wearing myself out, bought from MFJ (MFJ-1777 http://www.mfjenterprises.com/Product.php?productid=MFJ-1777). The Zepp antenna is sort of the original end fed, and can be tuned for any band up from the fundamental.

34617. Odd antenna configuration question

Yahoo group: ham-antennas (2014)
Date: 2014-11-08 14:50:29 UTC
From: wd4aon@...
Topic: 34617 Message: 34617

Hello All,
I have a summer home in upstate NY state USA that was a one-room schoolhouse built in 1839, built on a tiny, hillside lot. Since this is an historic building in a rural neighborhood, my only zoning/architectural control committee is She Who Must Be Obeyed. A 'wire antenna' has been authorized. At my age (72) I'm not going to do any experimentation climbing in the trees.
The lot is triangular, running uphill to a point at the rear. Two very large old maple trees are disposed about 20 feet apart at the front. They are about 35 feet to their peaks. I have just had an eyebolt and rope installed in the taller one that provides a clear run to a much higher locust tree at the rear point pof the lot. The distance between the eyebolt and the locust tree is about 70 feet. The top of the locust tree is probably about 40-50 feet higher than the top of the maple tree due to the greater height of the locust tree and the uphill slope of the underlying hillside. The line between the trees is roughly East to West.
I can get a fan dipole up for 40M through 6M, a Zepp, a doublet, or a triangular loop (fed at any of various points). I have a couple outdoor autotuners capable of handling the power I expect to use. I pretty much need to feed the antenna via autotuner fed by coax. The autotuner can be located very close to the loop feed point, and I have a length of 450-ohm windowline for the other atnennas.
I'd like to try to get on 80M, but that might involve a compromise shortened/loaded dipole in the attic where I can get to it for adjustments.
First question: If I use the fan dipole, Zepp, or doublet, what is the effect of the upward slope on impedances, directionality, etc., given the increasing elevation above ground at the intended bands?
Second question, what is the collective opinion(s) on which type of antenna to try first?
Anxiously awaiting some reasoned responses,
73

I just watched this and it is great. I am an 'old' science teacher/ recently reclassified as technology director. It is a constant source of irritation to hear things like 'children earn differently today' and 'I can't teach without technology'. My belief is we put men on the moon with guys educated in o e room school houses and chalkboards. I think chalkboards still have a place, I think old overhead projectors are great for shooting magnetic fields and I believe one of the three teachers that have been in my old room threw out a decide very similar to the one he used in that film. It was too 'old fashioned'.
Thanks for the link, I'm going to go out and get to working on some of my old fashioned stuff.

From: siegfried jackstien
Topic: 34617 Message: 34619

Try a ladderline fed doublet ... works all bands (also useable on 80 or topband

If you can not erect a triangular loop ... what about a triangular dipole (bent dipole)???

Feed from upper point and downwards to your 2 trees in the front (bent innerwards from there and then connect the 2 ends with some thin rope

Climbing trees is not needed if you have an "antenna launcher" (compressed air tennis ball cannon)

www.antennalaunchers.com

(just stole the idea and built my own one)

34621. New RF interference killing RX at my QTH

Yahoo group: ham-antennas (2014)
Date: 2014-11-08 17:34:23 UTC
From: Goldtr8 (KD8NNU)
Topic: 34621 Message: 34621

Dear Group
I need to make a noise finding antenna that I can take in my vehicle to look for a source of noise on 160m and 80m bands. My google searches have not yielded much information on something I can use on these bands or what I found was not clear to me on how to make one. My plan would be to make something and then use my mobile setup to drive and try to find the source.

Please any recommendations will be highly welcome.

What I do believe is that its something that gets turned on in the night hours as its not there during the day and there are times at night when it goes away.

Thank in advance for your help.

Cheers
Don

Don,

You might get away with taking an AM transistor radio, tune it to a high unused frequency and sniff around with that.

I ran the numbers on a 1-foot magnetic loop for your experimenting too.

Hmmm central heating system that is powered from night time (cheaper) power???

And when it is not tooo cold the unit does not switch on (or maybe a solar heating system is also used and in a sunny day the heat pump does not need to be switched on at night) ...

Just a shoot in the dark (but you should keep your ears also open when driving around)

Dg9bfc

Sigi

Ps ... any mw radio should work ... ferrite rod antenna can be used to null out signal

If the noise is coming from the power lines you will find that it travels quite a distance on HF frequencies making the isolation of the source difficult.
On VHF and higher power line noise does not travel as far, hence listening on 2 meters with a receiver capable of AM reception or an aviation scanner in the 120 Mhz range will give you a better shot at it.

MFJ makes a power line noise meter which comes in both a simple dipole type antenna arrangement mounted on the instrument or with a external small beam antenna for getting a better direction indication.

http://www.mfjenterprises.com/Product.php?productid=MFJ-852

The ARRL web page has a lot of information, to start
http://www.arrl.org/power-line-noise-faq

Of course the noise could be caused by other sources... look for switching power supplies including those found in plug in "wall wart" power supplies on consumer electronics like routers, laptop power supplies etc..... Dimmer switches, thermostats, almost anything that is powered.

The first thing I would do is to turn off the power going to your main power distribution box in your home and see if the noise is still there.. If not, the source is somewhere in your home.
If it is still present start looking elsewhere.

Since this is an historic building in a rural neighborhood, my only zoning/architectural control committee is She Who Must Be Obeyed. A 'wire antenna' has been authorized. At my age (72) I'm not going to do any experimentation climbing in the trees.
> The lot is triangular, running uphill to a point at the rear. Two very large old maple trees are disposed about 20 feet apart at the front. They are about 35 feet to their peaks. I have just had an eyebolt and rope installed in the taller one that provides a clear run to a much higher locust tree at the rear point pof the lot. The distance between the eyebolt and the locust tree is about 70 feet. The top of the locust tree is probably about 40-50 feet higher than the top of the maple tree due to the greater height of the locust tree and the uphill slope of the underlying hillside. The line between the trees is roughly East to West.

You need to eliminate the effects of the hillside in any calculations.
Radio waves don't respond to the gravity of the earth in any significant
way. So if you have a 20 degree slope and a 30 degree slope to the antenna,
you really have a 10 degree slope over local terrain for the antenna.
This assumes the hillside is uniformly sloped over several wavelengths.

> I can get a fan dipole up for 40M through 6M, a Zepp, a doublet, or a triangular loop (fed at any of various points). I have a couple outdoor autotuners capable of handling the power I expect to use. I pretty much need to feed the antenna via autotuner fed by coax. The autotuner can be located very close to the loop feed point, and I have a length of 450-ohm windowline for the other atnennas.
> I'd like to try to get on 80M, but that might involve a compromise shortened/loaded dipole in the attic where I can get to it for adjustments.

You could load the outdoor antenna, too. You might get away with a relay
or two, too, to switch the loading in/out from the shack. After all,
you're going to have control cable and power to the autotuner, right?
But we're starting to talk about quite a bit of weight up at a typical
dipole feed point. It might sag more than you like. You might need heavier
or copper clad steel wire to take the tension needed to reduce
sag, or a mast or other skyhook at the feedpoint.

> First question: If I use the fan dipole, Zepp, or doublet, what is the effect of the upward slope on impedances, directionality, etc., given the increasing elevation above ground at the intended bands?

Very little effect, IMHO. The antenna will tend to favor the downhill
direction, slightly. Impedance will change, maybe go down a bit, relative
to one parallel with the ground and at the same average height. THis depends
on the height. I only ran a dipole at 15 meters height at its feedpoint.

Note that you will have an elevation angle downhill that is relative
to terrain, not distant horizon. I.e. "DX"-favoring. Uphill, the opposite.

> Second question, what is the collective opinion(s) on which type of antenna to try first?

No opinion.

Hi. We have identified a source of interference coming from new, or newer home furnaces, heap pumps, etc. It turns out that many of the newer domestic heating units for houses have Chinese made switching power supplies that drives the fan, or exhaust fan. You mentioned yoiur interference comes in the evening.

I wonder if you, or a neighbour, has a new furnace, AC unit, heapt pump????

73 John Good luck.

Hi Terry,

First off welcome to the group.

Second, we are nitpickers about needing to know what you want to use the antenna for????
What bands, etc.
The group is loaded with hams with alot of experience in antenna design, but as a general rule we avoid open ended requests for help when we don't have enough information to really help you. So if your passion is 160 vs say 10 meters, the answers will be considerably different. Let us know what you want to do. Good luck on what seems like a neat QTH, with rock walls he he.

Cheers,

Mel, K6KBE

34630. First impressions G7FEK antenna

Yahoo group: ham-antennas (2014)
Date: 2014-11-08 21:42:41 UTC
From: Keith Heimbold
Topic: 34630 Message: 34630

I built the G7FEK as close to spec as I could and I have a couple interesting observations. The antenna appears to be pretty good on 80m where I almost worked barefoot this morning the W1AW/KH8 barefoot 100W this morning with it at about 25' Inverted V configuration (he heard my Zulu Zulu and kilo) and I heard a Japanese station very loud on 75m. I was very surprised.

I put both a 1:1 and 4:1 balun at the feedpoint and been experimenting on which bands tune better with the two different feed points. I have built a lot wire antennas since we moved and this one seems better than the inverted L so it will stay awhile. More experiments to come. I am not done trying things out yet, a horizontal loop will come before too long.

Hi,
I would start by characterizing the RFI... See:

http://nk7z.net/rfi-now/

For information on tools to do this, and some processes. There is a
part II up already, and a Part III which I am working on...

Also see Tom Thompson's site for how to construct a really good loop at:

http://tomthompson.com/radio/ReceivingLoop/loop.html

From: email4utoo@...
Topic: 34633 Message: 34633

I have extra tuner , XYL says make room , cause i am building an amp in our , "Hobby Room", yah i call it the Shack , but we ,"Share " it , hihi. i have two in very good condition, Sa2060a, yah the ones with the meters on the front and balun inside , comes with original manual not bs download copy. Full limit well made , has connectors for ladder line, single wire , coax, and bypass switch. clean inside non smoker, rather got to someone here to use and needs one of the Best ever made . Many say with tune a hanger, a tuna can, or a Rock if you can put a connector in it , hihi. email me off site , good on QRZd, we own our own place and i frequent the HHHnet ,and 40 meters . 73s, AJ W5HEH

yah i like mine as well, 138ft long about 44ft one side OCF up maybe 30ft , i work 80-10 ,barefoot, most of the time with internal tuner . does yours use a 4-1 Balun ? I spoke to BC last night on 40m, and have QSLs from OZ , Italy , and Panama on the way, also spoke to DE, cuba, Carribean, all on 40 barefoot , just now building an amp slowly to use occasionally . Also planning to build a Full wave loop soon before winter hits . Enjoy the OCF , 73s, AJ W5HEH

Its not in my house I but something external. Its not a plasma TV as I know that noise well as I have one of those suckers that I want to get rid of but the XYL is a problem with that right now.

It is ground wave received as its strong on my inverted V dipole and vertical but is not present on my big loop which is horizontally polarized. I understand from reading on w8ji that ground wave interference looses it horizontal polarization as it travels over ground. It is also not present on 40m and above on any of my antennas but only on 80m and 160m.

Right now I am thinking its is fairly close to my home within a couple of miles as I can tune to one of the dominant frequencies in my mobile rig and it gets louder in the area in which I live. However it has to be present to hear it and early in the evening its not heard at the house or on the mobiles.

Gud Luk to u OM!!! I have been "living" with a 60" Panasonic Plasma that moved in next door on Sept 28th.
It's running 50 to 60 db over on 160 & 80 meters, with an S-2 to S-3 on certain spots of 40 Meters. I tried every trick I know, and improved my station ground down to 3 ohms with a Megger. (I put in a Wheatstone ground...at a cost of $100+) That improved it by about 10 db. After her STILL saying it wasn't HER problem...I filed a complaint with the FCC. 40 days later I had a mobile RFI vehicle at my house. She hasn't been served with official papers-yet. But they left a notice on her front door of "illegal spurious RF radiation." The field engineers that were here told me that they had to report back their findings to the bureaucratic "bosses" at the office. IF they send her a registered letter, she will have 45 days to respond...before they go to the "next level."
FYI- The vehicle that was here last Wednesday (11-5) was a completely unmarked Suburban, with regular Maryland plates on it. I also found out that the FCC doesn't "own" the vehicles on paper. They are registered to the Dept of Homeland Defense. Go Figure. The 8 bay antenna array's are mounted in a fiberglass roof over the rear of the Suburban. They can electronically be phased and/or attenuated by computer control. In my case...the TV was 30 ft. from my house, and they had to electronically "cut" the signal by 40 db...just to get a null by turning the TV in 20 degree increments in a clockwise rotation. I WAS impressed! They also said Panasonic & Toshiba were the worst offenders. They have zero shielding on their plasma TV's. I asked how they got type 15 acceptance....all I got was "smiles."
They were here a total of 22-23 minutes. needless to say...I own't be getting a Christmas card from her this year!
It may take AWHILE for my solution to wind it's way thru the bureaucracy of the system...but you got to start somewhere.
Gud Luk...I REALLY mean that!
73,
Dave-KJ4PF

Sehr geerhter Herr Sigi,

Thanks for your suggestions. I was hoping for commentary from Europe since the gardens there are often small like my schoolhouse property.

I was thinking of trying a triangular loop, fed at/near the top of the maple tree, horizontally across to the locust tree, up to the top of the locust, and back diagonally down to the feed at the top of the maple tree. If I recall my antenna theory (from 1960), that would be horizontally polarized with the maximum height at the far corner. Alternatively, a triangle could be fed from the eave of the schoolhouse (at about 14 feet) diagonally in both azimuth and elevation up to the maple top and then diagonally up to the locust top, and then diagonally in both azimuth and elevation back to point of origin at the eave. A lot of it would be partly horizontal going out from the feed point to the top ends. This would give weather protection to the autotuner, easy access, but who knows what characteristics?

The doublet would allow the autotuner to mount at the eave, and my available windowline could feed the doublet. However, the doublet would run upwards from the low end to the high end at a significant angle, and since the doublet style is to be equally balanced to be effective, how would I make it have equal impedances with unequal ground reference distances? And what directionality characteristics?

The two maple trees in the front yard would form a very narrow angle to the locust tree, which is at the most remote distance from the shack and hardest to string the feed line. Also, the run from the locust to the maple which does not yet have an eyebolt runs in a line where the bell tower lies. Further, medium high voltage power lines run through the maples on the street side, and I don't want to go messing with high voltage power lines, so I can't shoot a line over with a tennis cannon.

I have no midpoint to hang the doublet/dipole center from.

What I was really hoping for was some commentary about the directionality, and other characteristics resulting from the end to end angle with respect to the ground reference.

Was sagen Sie?

Mit freundliche grusse und 73,
Terry

I have been watching this thread with interest. Last Sunday evening, 11-2-14, when I turned my transceiver on, I was met with sever RFI. This has been going on all week at all hours of the day. I am receiving it across the 160M, 80M, and 40M bands. Each band has a reading of 20 to 40 over on the S-meter. I have not been able to transmit successfully since this began except intermittently. It seems that my transmissions are very light and lost in the noise. So now, I am frantically searching through my RFI Book to see what I can glean. If any of you have any ideas for a starting point I would definitely like to hear about it. Well, off to find my portable am radio!!

"It seems that my transmissions are very light and lost in the noise"

That's odd ... your Tx power should not be affected by RFI .... if
that's the case .. it might be a radio problem ....

34642. RE: [ham-antennas] New RF interference killing RX at my QTH

Yahoo group: ham-antennas (2014)
Date: 2014-11-09 04:59:29 UTC
From: Larry Taylor
Topic: 34621 Message: 34642

I use to do this for a power company and look for TVI's that Hams would call in.. The best Antenna we found was a bent peace of antenna rod that was laying flat on the roof but not touching it. Mag mount ant on the roof would also work folded flat. We used a Zenith Short Wave Receiver and start out on the lower freq's and when we got closer you could pick it up on the higher freq's. Another power company would just drive around using their AM band radio tuned to a none radio station channel and listen there. With the power company the main problem was loose hardware that's in the powerline magnetic field. Street lights that flicker on and off. The Majority of the TVI were at homes. Here is a list of things I found. Door bell transformers, Light dimmers turn down but not off, Fish tank heaters, Electric blankets, Electric heating pads, old thermostat used on heater. Things that had Bi Metal contacts to turn and off items. The very first thing I would do would take a portable radio out to the power meter and put it nearby. When the noise was happening turn off 1 breaker at a time until there all off. This eliminates your home. You know it could be in your neighbors home too, so stay good friends with them and get there permission if you plan on doing the same thing with their breakers.

Subject: [ham-antennas] New RF interference killing RX at my QTH

Dear Group

I need to make a noise finding antenna that I can take in my vehicle to look for a source of noise on 160m and 80m bands. My google searches have not yielded much information on something I can use on these bands or what I found was not clear to me on how to make one. My plan would be to make something and then use my mobile setup to drive and try to find the source.

Please any recommendations will be highly welcome.

What I do believe is that its something that gets turned on in the night hours as its not there during the day and there are times at night when it goes away.

Thank in advance for your help.

Cheers

Don

500 watts into the antenna on 6 meters will do a good job of getting them to turn the set off! We had a plasma move in next door to me, several years ago..50 Mhz suddenly got hot..(AHEM).2 days later, Best Buy was out, picking up the TV and delivering a different type. *It* was quiet! <<EVIL GRIN>>

To all,

In the files section K6KBE listed in his folder K6KBE EZNEC files an OCF antenna file called OCFportabledipole.EZ.

In the design on segment 9 on wire #1 there is a reactance of 20 ohms. What is the purpose of this reactance?

Tks,

Joel – N3GSE

OK, I turned off all of the power in my unit (I live in a 4-plex). The interference could still be heard on the am radio. Turned the power on gradually and still no change. Went back up to the front of the unit, all of a sudden when I turned just the right way, the interference got stronger. I turned 90 deg to that and less interference. I turned 90 deg again and the interference got stronger (this was 180 deg to the first sounding.) I again turned everything off in the front and turned them on one at a time. The interference did not change. I next went outside (boy does AM radio come in well outside at night) and heard the radio with very little interference. The further I moved away from the building the less interference I got until it was gone. Talked to two of my neighbors, they stated that they have no new electronics in their units. I am open to any and all suggestions.

Give me your exact location and I take a closer look with google earth ...
then I can tell you maybe a bit more

Not easy to follow your description without having an idea what tree stands
where etc.

AVOID THOSE DAMNED POWER LINES!!!

It is just too dangerous to hang an antenna close to them (but you sure know
that)

About directivity and feeding impedance of your planned setup

I would need some more details to model such a setup in mmana (length and
heights of all points) ...

>
> I was thinking of trying a triangular loop, fed at/near the top of the
> maple tree, horizontally across to the locust tree, up to the top of the
> locust, and back diagonally down to the feed at the top of the maple tree.
> If I recall my antenna theory (from 1960), that would be horizontally
> polarized with the maximum height at the far corner. Alternatively, a
> triangle could be fed from the eave of the schoolhouse (at about 14 feet)
> diagonally in both azimuth and elevation up to the maple top and then
> diagonally up to the locust top, and then diagonally in both azimuth and
> elevation back to point of origin at the eave. A lot of it would be partly
> horizontal going out from the feed point to the top ends. This would give
> weather protection to the autotuner, easy access, but who knows what
> characteristics?
>

TRY THAT OUT AND SEE THE RESULTS ... OR MODEL IT IN MMANA

>
>
>
> The doublet would allow the autotuner to mount at the eave, and my

> would I make it have equal impedances with unequal ground reference
> distances? And what directionality characteristics?
>

Doublet is also effective if both ends are not exactly equal

Yes the ladderline will be better balanced with both ends exactly the same
... but if not ... who cares?!?

If you can hang a topband loop then go for it ... if you only have room for
an 80m loop then I would make it a doublet and not a loop (with a good tuner
an 80m doublet can be used on 160)

> The two maple trees in the front yard would form a very narrow angle to
> the locust tree, which is at the most remote distance from the shack and

>

SAFETY FIRST :-)

>
> I have no midpoint to hang the doublet/dipole center from.
>
>
> What I was really hoping for was some commentary about the directionality,
> and other characteristics resulting from the end to end angle with respect
> to the ground reference.
>
>
>
>
> Was sagen Sie?
>

I need more details ... then i can run some simulations

....

I would say ... if you have a nice location for the tuner ... then start to
go from there ... cause ladderline is nearly lossless you then have
different options what to hang ... and in what direction ... where
feeding-point is located etc...

So ... if you tell me your location ... I take a look in google earth ...
then tell me some heights and distances (after another email exchange maybe)
... and then I do some simulations

Dg9bfc

Sigi

Ps if it is ok for the group we do that here ... if not then we can do that
email exchange offline (off group ... in direct mail)

Hey Julie

Couple thoughts.

Log onto the ARRL website and listen to the Sounds of RFI audio files, there's lots of home appliance files as well as other things.

And since your am radio is working directionally, draw a pic of the building footprint and draw lines thru 3 or 4 nulls to see if they converge somewhere. And if it's easy, put the radio on a painters pole and see if it's up high or down low. None of this works too well if the noise is being radiated thru a cable or power line but you might get lucky.

And then there is the old data log if the interference ever varies. Time of day, day of week, outside temperature, wet dry, etc.

Not sure where you are at but here in Chicago it's not unusual to see seasonal variations when it starts to get cold or warm.

Good luck.

David , I can sympathsize with you and your woman next door . The offending TV in the fellers own home is his fault . His wife surely goes out without him from time to time . Frying a TV reciever should be no challenge and the replacement should be Hobby friendly or ELSE ! I once had a woman next door that would not allow the Feds to insp. She was on Rabbit ears seventy -five miles and across Dallas drom the TV transmitters. She also had telephone problems on her telephones that she got at the local gas station with a fill-up. I once knew a friend that removed tunes from a TV set while his wife was away .....when she returned to a non working TV she called the repairman . The repairman picked up the TV , reinstalled the missing tubes and redelivered the TV to the friends new apartment . We men must stick together ! Chuck Wq5B

Dave:
Look at the following to help you understand just what a Wheatstone Ground is.
Basically I put 3-30 foot copper grounds down in a triangle, spaced 8 foot apart, with a 6 foot ground in the center of the triangle. These are all tied together with #2 copper wire to "bridge" the ground rods together. The system in Florida had Caldwell connectors. Here I just used GOOD compression ground clamps, as I don't plan on it being a permanent install. Your ground wire to your station is fed from the point where all the ground wires are tied to the center ground rod.

Ground Resistance Testing:
http://www.electrotest.co.nz/Technical+Papers++Downloads/Technical+papers.html

The Original article I used to develop the ground system i used in Florida (sand as ground). This is what
Florida Power used in their substations. Good enough for them...was good enough for me:
http://blog.jmtestsystems.com/index.php/6-simple-steps-to-design-an-economical-grounding-system/

You might want to read this MIT article too:
http://web.mit.edu/~jhawk/tmp/p/EST016_Ground_Loops_handout.pdf

Hope these help!

Julie:
Go to YouTube. You can do a search for "RFI Noise on Ham Radio" You can then listen to different noises till you find out WHAT type of interference you have.

You can start here:

http://www.youtube.com/watch?v=Z8KcQdiL8Sw

http://www.youtube.com/watch?v=eH_HhcjdCH0

AND..my problem with my "new" next door neighbor's 60" Panasonic Plasma TV! (Sounds exactly like THIS!)

Subject: Re: [ham-antennas] Re: New RF interference killing RX at my QTH

I have been watching this thread with interest. Last Sunday evening, 11-2-14, when I turned my transceiver on, I was met with sever RFI. This has been going on all week at all hours of the day. I am receiving it across the 160M, 80M, and 40M bands. Each band has a reading of 20 to 40 over on the S-meter. I have not been able to transmit successfully since this began except intermittently. It seems that my transmissions are very light and lost in the noise. So now, I am frantically searching through my RFI Book to see what I can glean. If any of you have any ideas for a starting point I would definitely like to hear about it. Well, off to find my portable am radio!!

Good Info! Back in the 80's & 90's door bell txfmr's were the number one problem I had. (even though I was a Sheriff's Deputy, I worked for Florida Power (now Duke Power) too.) Cops never get rich...most of us worked a 2nd job to pay the bills.
Today most door bells are wireless and the problem has slowly disappeared. Now where I live, people put up electric fence's to protect their summer garden's from deer. The CHEAP ones create a "popping" noise.
RFI problems change from region to region...they NEVER go away!

I use to do this for a power company and look for TVI's that Hams would call in.. The best Antenna we found was a bent peace of antenna rod that was laying flat on the roof but not touching it. Mag mount ant on the roof would also work folded flat. We used a Zenith Short Wave Receiver and start out on the lower freq's and when we got closer you could pick it up on the higher freq's. Another power company would just drive around using their AM band radio tuned to a none radio station channel and listen there. With the power company the main problem was loose hardware that's in the powerline magnetic field. Street lights that flicker on and off. The Majority of the TVI were at homes. Here is a list of things I found. Door bell transformers, Light dimmers turn down but not off, Fish tank heaters, Electric blankets, Electric heating pads, old t hermostat used on heater. Things that had Bi Metal contacts to turn and off items. The very first thing I would do would take a portable radio out to the power meter and put it nearby. When the noise was happening turn off 1 breaker at a time until there all off. This eliminates your home. You know it could be in your neighbors home too, so stay good friends with them and get there permission if you plan on doing the same thing with their breakers.

Damn! I like your line of thought. Guess I need to become "active" on 6 meters. I just "hope" I can get into her cable feed. Hummm! Maybe a "loose" cable connector (or ground?) <more EVIL grin>
In another year...you won't be able to buy a plasma. But waiting for all the one's out there to DIE...is another problem.

73,
Dave-KJ4PF

500 watts into the antenna on 6 meters will do a good job of getting them to turn the set off! We had a plasma move in next door to me, several years ago….50 Mhz suddenly got hot….(AHEM)…2 days later, Best Buy was out, picking up the TV and delivering a different type. *It* was quiet! <<EVIL GRIN>>

I should clarify a few things. I used 3/4 inch copper water pipe for my "ground rod's". I soldered a hose connector onto a 2 ft copper pipe, (as my aquifer feed pipe.) I then soldered that to a 10 ft section of copper pipe. Turned on the water and let it slowly aquify into the ground until about 3 feet remained. I then unsoldered the feed pipe, put a connector between the next 10 foot piece, soldered the connector, and did it all over again. it took about an hour per 30 ft ground pipe to "git er done". The ground where I live is pretty hard after the 1st 8 to 10 feet. And I don't even know if civilian's can find/buy a 30 foot solid copper ground rod.
I figured I better clarify...before everyone thinks I "am full of s***" Like my other half is so fond of using, as a term of "endearment" during adult discussions.
The married guys know what I am talking about...you single guys WILL "learn" in time.

I wonder,

what if any study has ever been done in grounding, what is better or if
it makes any difference even,

Say a ground rod like this 30 feet down, just one, a 30 foot long one.
in other words 30 feet deep?

Compared to a same diameter copper conductor also 30 feet long, but not
vertical bur buried say 1 foot down.

it still has 30 feet of earth touching.

Anyone?

And even if you were to get through those rocks, they are terrible
conductors, so your grounding benefit from all that work is little to none.
Hense the question I just posted,, if not deep how about horizontally?

Interesting! Now you got me THINKING!
As far as for Power Company's and 60 Hz. Vertical grounds are the way to go.
For RF, most radio and TV stations go horizontal with their grounds.

For me, my RF "problem" is saturation from a plasma TV 30 ft away (next door.)
I will say the better ground, and a few other "tricks" did cut the RFI...by about 10-15 db.
But that only brought it "down" to 40+ db.
I am waiting to see what action the FCC administration takes with her, after their "visit" last Wednesday. (11/5.) Clearly her TV is in violation of the FCC Part 15 Acceptance sticker they say is on the TV.

Depth beyond a foot or so doesn't get you anything, supposedly, for
a RF ground, but it is what you want for lightning and power ground.
Going horizontally or diagonally is less desirable. So I hear, anyway.

Right.

Our electric co (and the NEC IIRC) says that if you can't get the entire 10' ground rod in, then in get as much as you can then bend the rest over - or try diagonally. An alternative is to use a large sq in copper plate burried about 18" deep.Around here we have lots of granite in the ground due to glacial activity so it is difficult at times to get our ground rods the full 10', though I was lucky when I moved my elec svc for the house, I used a rotohammer with a ground rod driving attachment and got all mine in the full length.

Would you be able to put up an inverted L?

I am currently working on this antenna:

http://www.qsl.net/hb9mtn/hb9mtn_h-pole.html

I just built my 600 ohm feed line last night and the cross arms yesterday
were drilled to accept the antenna wire. Hopefully I'll be able to get the
rest assembled this week.

From: schwartzj22@...
Topic: 34644 Message: 34668

Mel,

Wow, this raises more questions for me. Sorry about all these questions. I have done lot of modeling but have not yet employed resistance or reactance in the models.

Is this a reactance that is part of the actual physical antenna?
Is this a reactance that is only part of the modeling?
Is this reactance capacitive or inductive?
By sweet spot do you mean that by plugging in a specific amount of reactance (I guess either capacitive or inductive) in the model you can tune within a band for low SWR?
Once you know that right value of reactance do you then physically modify the antenna?

Tks,
Joel - N3GSE

OK Joel,
First, I have built and tested the antenna with a AIRDUX coil with a jumper strap to set the frequency of interest. Later I put in a variable inductor with a gear motor drive. I have re-moted the control so I can tune the antenna from the operating position. It is a permanent part of the antenna now. Yes the reactance is part of the total wire list.
Yes, depending on where you design the antenna, you can use either cap or ind. I have done both. If you want to use a cap design it for the bottom of the band, for inductor, design it for the top of the band.

I leave the reactance in. I do not change the physical antenna. Pictures and word document explaining the design available of the fixed and variable version. Glad to share.

Well I made some progress tonight on the way home.

I used my mobile rig with hamsticks to listen while driving on the way home from work. I tuned to 3.902 which is a very strong frequency that gets trashed at the home QTH and used a 40m hamstick as the receiving antenna. The idea for this setup was to be able to attenuate the signal as I got closer to it.

Anyway while driving home with the pre-amp on the IC-7000 when suddenly the noise was present and strong less than 1 mile from my house. I drove around until it got real loud and turned the pre-amp off and it went away. I then drove around with the pre-amp on until it was at about an s7 on the meter then turned the preamp off as I was close and then drove around until there was about 1 s-unit showing on the meter. I could hear the noise with the pre-amp off when close and the s meter small reading confirmed that I was real close.

The noise is clearly in one subdivision close to my house but I can not tell what is the source at this time. I also know the noise does not show up on the AM radio in the car although bad power poles do show up.

So to me major progress has been made, now I need to identify where in the subdivision or maybe what house this trash is coming from. Next short term step is to listen to the links several folks have sent to me to see if any of them match what I am hearing so I know what I am looking for.

I will keep the list updated as I learn more about the problem.

Cheers and thanks for the tips so far.

Several useful tools. 1) Tecsun PL380 -- a nice AM/FM/Shortwave portable, DSP IF, has built-in loopstick antenna. About $45. 2) A ham talkie that has wideband RX. My Kenwood TH-F6A does that and has a built-in loopstick antenna.

Hi Don,

Look for a utility water transfer pump station or a sewer pump station. All the new pumps are Variable Frequency Drive (VFD) to save energy costs and that generates RF if not properly filtered at the source. The other issue to watch is that such pumps do not run constantly, so will shut off and then ramp up slowly when required, so the interference may change frequencies and/or intensity as such pumps cycle.

The same can be true for local water and irrigation wells in rural areas.

Conventional water and sewer transfer pumps can do the same sort of thing when the internal laminations start working loose and shifting the magnetic fields randomly.

Commercial utility power regulators can be a source of such interference too. Generally they will be a series of three pole mounted transformer looking devices installed along a rural power line, but not near any residences or major structures.

Hello Don

You have found a location where the noise is really strong??? So then try to pinpoint it with a small receiving loop (fox hunting style)

That loop does not need to be resonant (cause you do NOT wanna transmit with it)

A 3-4 feet wire ... turned into a loop ... and then connected to a short coax should do the job

Sometimes these noise sources also show up in vhf or uhf area (if you are really close!) so then also a beam and a "scanner" could be used to find exactly the noise source

Good luck

Dg9bfc

Yes, but the VHF/UHF receiver must have an AM detector and an "S" meter.
An FM detector will not be much use.

Ken / Don,

The MFJ-852 is a single-frequency broadband AM receiver operating in the 135 MHz region.

I just bought one ($119) and received it today. I also have an RFI problem.

Bare stranded copper wire, picks up moisture, with airborne pollutants, which induces corrosion. Use insulated wire. As for wire suppliers, just get a roll of insulated black primary wire from your local auto parts store. Lots of the fancy name wires, being peddled by amateur radio supply stores, is nothing more than farm electric fence wire, or welding wire. Same thing with insulators. If you want electric fence wire, or insulators, go to your local farm store. It,s about $20 for a 1000ft.

If you want insulated stranded copper wire, (best choice) that is UV resistant, go to your auto parts store. Primary wire is used to wire boat trailers, autos, RV,s etc etc. It is good stuff, and has not been repackaged under a fancy amateur radio title.

Ken,

Electrically, I've seen very little difference in EZNEC results modeling with both types over the years and zero difference in practice. There would only be mechanical issues as discussed in the posts already posted. I've seen insulated stranded wire pick up moisture and get corroded, so there are always trade-offs.

Hi,

I read somewhere on the internet that the "THHN" insulation reduces the velocity factor by about 5%. Thus the antenna (dipole) needs to be about 5% shorter than calculated.

Anyway, I always cut for the extreme high end of the band and then at each end add a short hanging wire from the antenna. This makes tuning easier since the hanging wire can be trimmed and/or twisted back on itself. It avoids the need to "fiddle" with the wire on the end insulators.

That's the reason Ward Silver (N0AX) suggests using the formula 492/f when calculating the wire needed for a dipole, so you have that extra length added in from the start.

I usually cut wire for low end of band, place insulators at the length of the upper half to 2/3 frequency, then let the ends hang down for cutting to desired frequency. Therefore no soldering of wire ends. I also cover the wire ends with RTV or coaxseal, same as middle to keep moisture out.
I had a 80 and 40 dipoles made with #12 solid house wire, fed with same coax and 90 degrees apart installed, that I used for over 30 years. I changed the RG8 to RG8x after 20 years. It was still working well when I gave it away when I moved.

But this is due to the length to diameter ratio, not dielectric loading. If you crack open the ARRL Antenna Book to the section of Antenna Fundamentals you will find that length to diameter ratio is heavily based on the reactance for a given diameter of conductor and not about the dielectric loading on the conductor, although there may be a small loading effect it is overshadowed by the first order effect of the L/D ratio.

Extremely thin wires for a given wavelength will experience higher reactance variations over frequency.

The beauty of copper is that the copper oxide that forms protects the wire and is conductive. It doesn't hurt at all.

Insulated wire is a bit heavier so it sags more and collects more ice in an ice storm. OTOH, you will get less static build up from charged rain and snow flakes.

Bottom line, it doesn't make any significant difference whether the wire is insulated or not other than the minor change in the velocity factor. Bare wire does make it a bit easier to adjust the length just by wrapping the wire back on itself.

Comparing Copperweld to fence wire or welding wire is totally wrong! Copper coated welding wire has a very thin coating and will not hold up over time. Heck, even inside the shop it may start to rust on the spool after a year or two. Copperweld is a much thicker coating. And it's not just the weather resistance but also the thickness of the copper for conducting the RF.

I have never seen copper coated fence wire at any farm store. Aluminum fence wire is soft and won't hold up over any distance without stretching (8-12' between fence posts.) It's also hard to solder and make good connections. Galvanized fence wire for antennas? No thank you.

If you want insulated wire, THHN from Lowes, Home Depot, etc. is reasonable. #14 runs $45 for 500' locally. You could get bare copper also but that's always soft drawn and you really want hard drawn copper wire for antennas. Soft drawn copper will stretch and change the frequency over time. Either get hard drawn copper or Copperweld.

I guess an autoparts store would be okay for wire for 6 or 10m, but I've never seen them have it in long enough spools for and 80 or 160m antenna. And they seem to be more expensive than Lowes.

I bought 1000' of that wire. I agree, it handles very nice. I needed a 600' length for my loop. One span is nearly 300'. I have my doubts that it will hold up to a heavy ice storm but I did want insulated wire to reduce the static build up from charged rain and snowflakes. (If I have a warning I will probably drop the antenna before an ice storm.)

Although the DXE wire is nice to handle, I don't know that it's any better than #14 THHN which is available locally at Lowes for a little lower price. ($90 vs $105 per thousand.) That THHN insulation seems pretty strong.

Personally I use bare wire in conjunction with Dr. Van der Graf Antenna Wax. I found it gives me a minimum of 23 dB gain. However, when you apply the wax, immediately wipe it down with a terry cloth rag to prevent the dreaded "antenna lock." (A little bit goes a long way!) Once I started using Dr. Van der Graf Antenna Wax, I no longer needed an amplifier so I sold it. I could not be more happy using Dr. Van der Graf Antenna Wax.

Lee, w0vt

PS: I have no financial interest in the Dr. Van der Graf Company.

I don't know, Mike. I called Dr. Van der Graf some time ago and was told this was proprietary information. All I know is it really works! I wish I would have known about it sooner as I could have saved a lot of time and money. At $23.00 an ounce, it is a real bargain.

Mike,

My thoughts are, it might be making the wire "oxygen free". This might be the secret.

To be honest with you, the Dr. Van der Graf Wax was making my signal so strong I was a little worried about FCC repercussions . I was thinking maybe they would suspect I was using illegal power. For that reason I "dampened" the results a little by placing a one pound magnet on each end of my dipole. (I made sure a had the N pole of the magnet facing one end of the antenna and I had the S pole of the other magnet facing the other end of the dipole. I did that to keep the proper phase relationship. That cut my gain down to around 13 dB which, to me, was more realistic. So far, the FCC has not been knocking at my door.)

I wasn't sure initially the magnets would "dampen" my signal but the final results showed indeed they did help reduce the signal. I think, what is happening, is the signal was "slipping" or moving down the wire from the feedline so quickly due to the Dr. Van der Graf Antenna Wax being so "slippery" that it was just giving me too strong a signal or final result. The magnets are repulsing the wave just enough to slow it down to the point giving me my wished upon 10dB reduction of gain. (The signal is still "slipping" down the wire faster then normal, but not as fast as when the magnets are not "in-line." (My Radio Shack Wave Meter confirms all this.)

You can make your own antenna wax very easy ... (dr van der graf will be maybe a bit angry if I tell that here)

Just buy some snake oil and boil it till you have a sticky wax

Then apply to your antenna wire

Can also be used as a q-dope for coils (if you cook some longer cause on coils you need a thicker layer of that wax)

From: Walt Wilson
Topic: 34681 Message: 34710

Way back when I was a 20 something year old and able to climb and experiment, I had a 70 foot crank up tower and a 5 element yagi beam that would make you wonder if it was being used with a barefoot rig. Without the benefit of DX I could cover over 200 miles with impressive results, talking to the next state almost daily. That was a fluke, not antenna oil

You can make your own antenna wax very easy ... (dr van der graf will be maybe a bit angry if I tell that here)

Just buy some snake oil and boil it till you have a sticky wax

Then apply to your antenna wire

Can also be used as a q-dope for coils (if you cook some longer cause on coils you need a thicker layer of that wax)

34712. TL with 4nec2 issue

Yahoo group: ham-antennas (2014)
Date: 2014-11-13 20:16:49 UTC
From: schwartzj22@...
Topic: 34712 Message: 34712

To all,

I have been modeling simple wire antennas with 4nec2. I then use N6BV's Transmission Line for Windows to get the impedance at the source (in my case at the tuner).

I recently added how to model with 4nec2 with a transmission line (TL). But I am missing something fundamental.

1) After modeling a simple dipole with a ladder line I realize that the results of the model run show a different impedance at the load than without the TL. Isn't it true that the load impedance should be the same with and without the TL?

2) What additional info should I be able to get with 4nec2 by including the TL?

I have all the 4nec2 instructional materials but do not see anything like this in them. Or, maybe I just missed something.

Any help is appreciated,

Joel - N3GSE

Back in the 1860s it was a very common commodity. Every traveling
medicine man had a gallon or two in his wagon.

Good stuff, when you could get it.

Dunno where one could find it these days. Probably at one of those Old
West towns that have been restored...

Joel,

Is the antenna input Z the same as the characteristic impedance of the TL? If not, you'll transform the Z with the TL. Time to get the Smith Chart out.

I used to work for a nationally known milcomm antenna and antenna test instrumentation company located north of Atlanta. Some of our hams tested the Dr. van de Graf Wax and found their advertising claims to be very optimistic. They tried various wires and alloys, but as best I remember (this was a few years back and in the springtime I remember 'cause the dogwoods were in blossom) they only got something like 12 db gain, and that was with a special copper coated silicon-bronze alloy wire. Regular soft-drawn copper wire was only improved by about 8 or 9 db. Something in the wax affected the alloy. But 23 dB was just way off -- false advertising!

ROFL

Sure you need vertical polarized wax for verticals and you use horizontally polarized wax for dipoles ... other wise you will loose 10-12 db (should be 20 db theoretically) ...

Myron- WVØH,

There is the impedance at the antenna (load) and there is the impedance at the source (the other end of the TL-input). I thought the transformation of impedance takes place at the source (because of the TL) and not at the antenna. I thought the antenna impedance (load) stays the same regardless of the TL line type and its impedance.

In other words, If the resistance and reactance at the antenna is R and X it gets transformed at the source due to the TL. If the TL is coax or if it is ladder line the resistance and reactance at the antenna still have the same values of R and X.

Do I have this wrong?

So what additional info, if any, am I supposed to get in 4nec2 by modeling with a TL? 4nec2 gives the impedance at the antenna but I can get this by modeling without a TL. Definitely I am missing something.

Tks,
Joel – N3GSE

Joel,

Yes, the antenna impedance (Z = R +jX) Ω does stay constant for a given frequency but the impedance transformation takes place along the TL, in fact the phase rotation along the line is responsible for the given V and I (thus Z) at any point along the line. So yes, the antenna Z is constant for a given frequency but the length of TL can vary the input impedance seen by the source just by lengthening or shortening it. Once you get past an electrical 1/2 wave length you start over. I created a spreadsheet with a MOD operator to "unwrap" TL lengths to multiples of 90 degrees so that I can figure out what phase rotation a particular piece of line has that is longer than 1/4wavelength for all my EZNEC-ing.

Since I'm not familiar with 4NEC2, just EZNEC, my experience has been that TL lines do not have physical properties, just electrical properties. Meaning you can have an antenna 30 feet above ground and a 40 foot TL even though it is straight up and down in the model. I keep forgetting to check my TL lengths and it leads me on some wild goose chases until I discover my error.

I'm not Myron, but if you change the surge impedance of the
transmission line the antenna's resonant frequency is changed.

A dipole that resonates at 7.05 MHz using 75 Ohm coax is too long for
that frequency when fed with 50 Ohm coax.
A 2 meter dipole (146. MHz) with 75 Ohm coax will be 19+19 inches, while
with 50 Ohm coax will be resonate at 146. MHz when it is 15+15 inches.

I know nothing about antenna analyzing software, but the impedance
and reactance of an antenna is partly the function of the frequency so
changing the TL surge impedance will change just about everything else.

The way I understand it, if the antenna's impedance and the coax's
surge impedance match, (at the frequency of interest) the length of the
transmission line will not effect the impedance at the far end of the
transmission line.

Partly correct Ron.

The part that is correct is your last paragraph, when all things are the same, the TL length matters not. The part that isn't correct is the part about changing the characteristic impedance of the TL changing the antennas characteristic impedance. It doesn't change anything about the antenna, it only changes the response at the input to the TL, thus an impedance matching device, a Q section, if you will.

Myron,

OK, I’m good with most of this now. Now for the specifics for my modeled dipole.

With no TL the load impedance at the antenna is 149+j231 (18.103 MHz). For the exact same antenna at the same frequency but with a 100 foot length of 450 ohm ladder line the load impedance at the antenna is 290+j459. Why did the load impedance change? We all agree it should be the same.

BTW-it is the same for 4nec2. You can have an antenna 30 feet above ground and a 40 foot TL even though it is straight up and down in the model.

So, for EZNEC what do you get that is different in the results by modeling with and without a TL? In 4nec2 all the results seem to be the same for with and without a TL.

Tks,
Joel – N3GSE

Joel, hold on a second. I have to get something straight first. Are you measuring the feed point Z in both instances with and without the TL attached measured at the antenna terminals? If so, that will change the feed point impedance because of the stub effect placed at that point. It's a tuning stub, so now with the TL attached it will cause the input Z to change if measured at the feed point. (The antenna input Z itself remains unchanged but it is now in parallel with another circuit, the TL) Somehow, I thought you were measuring the changed reading at the input end of the TL, in which case, it will change in accordance with a TL rotation around the Smith chart.

No, I believe that the model is accurate in as far as the tuning effect that the TL has when you measure at the antenna. Stub tuning, in effect.

When I model with and without a TL, I just get a value of changing Z based on the length of the TL. The input Z will fall on the circle created by the TL.

Let me see if I can create a screen shot of the Smith Chart App with you load and a series section of 450 Ω line. See attached.

I can create one with a parallel section (stub) as well.

Myron,

4nec2 reports the impedance at the load (antenna). I am not familiar with the stub effect. If my 4nec2 results are not in conflict because it is to be expected that the antenna impedance will be a bit different with and without a TL, then I am ok with this.

Maybe this is the advantage to using a TL based model. You get a more accurate antenna impedance. Then, using this impedance we can all determine the impedance at the source (tuner) and presumably it will be more accurate. You think?

I never use Smith Charts. I use either N6BV’s TLW3 or TLDetails by AC6LA. You get the same info but much much quicker.

Tks,
Joel – N3GSE

I do know as a fact that when I use a return loss bridge (with a RF
sweep generator and a real time display) the frequency that every dipole
that I ever tested loses the most sweep power to radiation is changed
when I change between RG-8 and RG-11 feedline and the change is not small.
I also know that when I adjust a dipole to the desired frequency
based on the length calculated using the formula in the ARRL handbook
with RG-11, RG-59 or RG-6 it is tuned "in the band," (using the return
loss bridge) but using RG-8 it is always below the band and I must
shorten the elements, by feet, to get it back in the band.
I also know as a fact that the length of any impedance of feedline that
I use, add or subtract does not change the frequency that every dipole
that I ever tested, loses the most sweep power to radiation.
Return loss bridge measure amplitude without any indication of angle.
Return loss bridge displays the reflected power and the lack there of.
Return loss bridge display match the reflected power that a transmitter
sees.

What causes these changes that I have constantly observed over the
last 40 years? (which also apply to 2 meter Yagi antennas)

Joel,

I think that the NEC implementation of TLs have been refined enough that the results are accurate whichever way they get implemented, so I believe your answer is accurate.

Yes, TLW and others are quick ways to implement TLs into any model. So no worries not using a Smith Chart. I use them because I'm more visual and like to see more of what's going on with the circuit along the TL.

And yeah, Google "antenna stub tuning" and see all the hits. Lots of info out there.

Ron,

No, no you are 100% correct. I misunderstood Joel and thought he had said that the antenna Z changed when he looked into the transmission line at the source end. I did not realize he was referring to looking at the Characteristic impedance at the antenna when the TL was attached, a stub if you will.

We can simplify this to a single example: say for instance we were to lay a 100-Ω resistor on a table and call it the antenna. Next we add another 100-Ω resistor in parallel, the circuit Z is now 50-Ω but the antenna (the 100-Ω resistor) has not changed. That's was the point I was trying to make, I missed the other details.

Hello Mel

You forgot one major point:

The glue (or a sticky wax) is needed for receiving (received waves stick to wire and travel along the wire towards coax connector)

The snake oil (for making the rf waves "slippy") is for boosting the transmitting signal (waves escape easier from the wire towards the ether)

That is also the reason why some hams use 2 antennas (one for receive and the other for transmit) ... one antenna is with glue or sticky wax (for receive) and the other antenna is "oiled" (for transmitting)

With cooking snake oil it becomes a sticky wax (as already noted)... so you can use one thing for both antennas (just depends on how long you cook it)

I am still experimenting with a snake oil bee wax combination (secret mix) that does the rx tx switching in the antenna

That snake oil makes the rf wave slippy ... and the bee wax melts when rf power is applied to the antenna ... so in transmitting the snake oil wins (rf power can escape easy from the wire)

... when you switch to rx the snake oil bee wax mix cools down ... and the bee wax wins (so wire becomes sticky for catching the rf energy out of the ether)

You gain 10-12 db in receive and about 18 db in transmitting

I could not get to the theoretically 23 db gain in transmitting cause I have a mix of both

And the best thing is that it also prevents ice loads in winter

:-)

I have string up wire antennas around the world and never wasted time striping insulation. They have always worked with no problems.

Subject: AW: AW: [ham-antennas] Insulated vs Bare Wire

Hello Mel

You forgot one major point:

The glue (or a sticky wax) is needed for receiving (received waves stick to wire and travel along the wire towards coax connector)

The snake oil (for making the rf waves "slippy") is for boosting the transmitting signal (waves escape easier from the wire towards the ether)

That is also the reason why some hams use 2 antennas (one for receive and the other for transmit) ... one antenna is with glue or sticky wax (for receive) and the other antenna is "oiled" (for transmitting)

With cooking snake oil it becomes a sticky wax (as already noted)... so you can use one thing for both antennas (just depends on how long you cook it)

I am still experimenting with a snake oil bee wax combination (secret mix) that does the rx tx switching in the antenna

That snake oil makes the rf wave slippy ... and the bee wax melts when rf power is applied to the antenna ... so in transmitting the snake oil wins (rf power can escape easy from the wire)

... when you switch to rx the snake oil bee wax mix cools down ... and the bee wax wins (so wire becomes sticky for catching the rf energy out of the

ether)

You gain 10-12 db in receive and about 18 db in transmitting

I could not get to the theoretically 23 db gain in transmitting cause I have a mix of both

And the best thing is that it also prevents ice loads in winter

:-)

Myron,

Thank you for the help. I am ok with modeling now with a TL.

I ran a simple test. I created a dipole very close to resonance (52.6+j0.3). Modeled it with with a 52 ohm TL/without a TL. Low and behold the results were very very close. Then did a model with 400 ohm TL. The results were definitely different but not hugely different.

Tks,
Joel - N3GSE

34754. FAA Site Antenna

Yahoo group: ham-antennas (2014)
Date: 2014-11-16 19:31:06 UTC
From: n8yss@...
Topic: 34754 Message: 34754

My Fellow Hams,
Came across this antenna a couple of months ago in my travels. See images I posted to photos in the group area under "FAA Site" file folder. The site appears to be some kind of unmanned radio station for the FAA (Federal Aviation Authority). Some warning signs cautioned of tampering with the equipment could cause loss of life. The station was near a small commercial airport in Manistee, Michigan, USA. I recognize the Yagis, they appear to be cut for the air craft band (118-136.975 MHz). I am wondering about the 2 parallel wire antenna(s) - the two elements are parallel. My guess is they are 40' in length and 2 feet apart and feed by coax, with the center conductor going to the one wire and the shield to the other wire. It does not appear to be two dipoles side by side. What is the wire antenna and how is it used? What frequency is it for? How could this be used for amateur application?

TIA and Happy Thanksgiving,

Jon, N8YSS

OK. Google NDB. You'll get a lot of hits. They are a lot of fun to "DX". The
NDB "band" runs from about 190 through 450 KHz or so. Most of them don't
run a lot of power, but can often be heard a long ways.

My greatest "DX" is one in far northern Canada, over 2500 miles from here.
That particular one runs 50 watts output. I was quite surprised to hear it,
given my terrible noise level here.

They usually run AM with a tone-modulated CW ID after a steady
tone-modulated carrier. The old designation for that mode was MCW, or
Modulated CW.

There are also several high-accuracy ground-based GPS stations in that
band also.

Topic: 34763 Message: 34764

Yes, run a wire that is attached to the top run down suspended about two or three feet away from the top of the tower and all the way down and place an air variable capacitor in series with the wire at the base to ground. Tune the variable cap with an RF current meter to obtain maximum current at the freq of interest and that's it. We had to detune an AT&T tower that was interfering with our nighttime pattern.

Ken,Thanks for the info. Looks like the NBD's could also be used by us hams a kind of DX beacon for 160, correct?
What about the FAA wire antenna? How would one cut one of these for the ham bands? It is a whole lot shorter than a 160 meter dipole antenna. Looks like someone with a normal city lot could put one up.

Hmmm ... ndb are at 300-500 kc (more or less) and 160m is around 1.8-2 megs

So ... for using as a dx beacon I would try to use a mediumwave station
around 1.5-1.6 megs ... that would better "match"

The TA-33 antenna is still in production so the parts, including the coil end caps should be available from Mosley.
I spent a week refurbishing my 30 year old CL-33. If your TA-33 has been around for awhile, it would be a good idea to disassemble the traps and inspect them for loose connections. I found the coil form cracked in one of the traps on my CL-33. There are several good step by step articles on the Internet that can guide you though the procedure. You might be surprised what you find inside them.
The trap end caps on my antenna were never replaced and they were all in good condition. So, I did not have to replace them.

An NDB antenna is vertically polarized with extensive radials in the ground and a twin wire capacity hat. At first glance one might mistake it for a dipole, but what looks like a feedline is the vertical radiator. It's far too short for a quarter wave, hence the tuning "hat".

Hello Gary et al!!

I've been reading these posts with some interest and thought I might be able to shed a small tidbit of light on the subject.

First of all, Mosley still manufactures the TA-33 Tri-Band Yagi in all it's variants, and all parts for these antennas are still available.
You can still purchase all the "pre-cut" aluminum tubing, as well as all plastic and or rubber parts used on the antennas. Mosley also has the Trap forms, both wound and unwound, as well as the completed Trap assemblies.
I just purchased new trap caps and boom end caps this month.

Mosley doesn't do much email. To contact them call 800-325-4016. The operator will transfer you to Gary, and he will take care of your needs. All you need is a credit card and a list of needed parts. :-)

They also had the few parts I needed for my Mosley 40 Meter Mono-bander that I'm reworking. I hope to get both of these Mosley units back up on the tower this winter!

Cheers and 73,

Jim wbt5wc

There is Gary Jr and Sr.

Jr. takes care of most operations surprisingly he is not a ham but an all around good guy.

I brag about Mosley often and anytime I see one for sale locally I may pick it up as I know it's a jewel in the rough and it may need some polish.

I know that when I'm done the antenna will perform and last for many years so the effort is worth it. No hose clamps with Mosley antennas.

You are best to phone them as Jim states and order your parts, they will have everything you need.

You can ask for the manual as well and you will be sent a pdf file.

IMHO, yes. Also for the "new" ham band at 630 meters. I have done only a
little NDB dxing, but it sure is fun. The nicest part about them is that they
identify themselves and there are extensive lists of them on the web, so one
can easily find where they are.

> What about the FAA wire antenna? How would one cut one of these for the ham
> bands? It is a whole lot shorter than a 160 meter dipole antenna. Looks like
> someone with a normal city lot could put one up.

As someone else mentioned, those antennas are vertically polarized with
usually a "capacity hat" on top, although not all of them have that capacity
hat, either. As was mentioned, that capacity hat can be easily mistaken for a
dipole or other type of antenna itself, but it isn't.

My own 160 meter antenna is my regular 55' tall 80/40 vertical with a
base-loading coil I switch in and out. I have worked Europe with it and 100
watts.

I am also a founding-member of the 600 Meter Research Group. Many of our
active stations use electrically short antennas with a capacity hat of some
sort.

We have an active forum if anyone here is interested in that band. There are
about 30 stations either active or listening on that band now. We have had
an experimental license, WD2XSH, for at least 10 years. There are some
details on QRZ.com under that call.

Several others have applied for and received their own experimental licenses
for that band.

BTW, I am a bit confused: are you dealing with an abandoned FAA station,
which is on property you own or have access to?

If so, I would leave the antenna exactly as it is and "adjust" the loading
system to operate in both the 160 meter band and the 630 meter band.

And, yes, all of the folks who are active on the 600 meter band are on normal
city-sized lots.

Several of the active stations have been copied literally all over the world,
and this with an ERP of only about 5 watts at most.

The propagation on 600 meters is very "odd", covering extreme distances with good signal levels when the higher bands are pretty much useless.

34780. Re: [ham-antennas] FAA Site Antenna

Yahoo group: ham-antennas (2014)
Date: 2014-11-17 16:29:26 UTC
From: Andy
Topic: 34754 Message: 34780

Looking at the photo, my first thought was either a folded dipole or a close-spaced beam, but those are wrong. The "feed" wouldn't be right for either of those. I think the previous replies are right.

In the early days of radio, it wasn't uncommon for antennas to consist of a vertical wire that connected to the center of two or three (or more?) parallel horizontal wires, which were stretched between the masts on the ship, or between buildings or towers. I think most early ship radio antennas were like that, as were many of the very early AM broadcast station antennas.

If you look closely at the FCC's seal, you might see what I'm talking about, but it is partly obscured by other stuff. Ignore the straight diagonal lines. Underneath the eagle holding the lightning bolts, there are three horizontal wires, and in the middle there is a "feeder" line that connects to all three, joins, and then drops generally downwards.

These days we recognize it as a vertical antenna with top-hat loading. What you think is the feedline, is really the radiator. It's one wire that splits into two or three. Those horizontal wires mostly don't radiate, but they are a capacitive load or tuning element because the vertical wire is much too short electrically. Currents in the horizontal wires are in opposite directions (away from the center point, same in both wires) so their fields tend to cancel, which is good because the antenna is supposed to be "non-directional", hence the N in NDB.. So this is like a "T" vertical antenna, but with two horizontal wires on top instead of one. The whole thing is fed against ground, probably a good radial system.

This is also what gives us some versions of the schematic symbol for an antenna, like the one at the top in the ARRL logo, with one vertical wire splitting into three.

I think this kind of antenna had a specific name, but I'm not sure. Some places call it a "Marconi antenna" but that name might be too general.

http://www.on8im.be/index.php/antenne-marconi-160-m
has diagrams of this kind of antenna for 160 meters. It is in French.

Regards,
Andy

Subject: AW: [ham-antennas] Re: Topband: New RF interference killing RX at my QTH

Hello Don

You have found a location where the noise is really strong??? So then try to pinpoint it with a small receiving loop (fox hunting style)

That loop does not need to be resonant (cause you do NOT wanna transmit with it)

A 3-4 feet wire ... turned into a loop ... and then connected to a short coax should do the job

Sometimes these noise sources also show up in vhf or uhf area (if you are really close!) so then also a beam and a "scanner" could be used to find exactly the noise source

Good luck

Update on my noise problem. It just went away on its own. I have the subdivision identified where the noise is from and I will build the simple loop and be ready for when it returns.

Myron,

What would be a suitable RF current meter ?
Would the MFJ-854 work OK for this ?

Thanks one and all for your thoughts onthe FAA site antennas. Sorry on the delay in my response. I am notretired, and my work comes in clumps. Yesterday was a long day!
Sigi, what would you suggest for betterbeacons on 160 M? Or do you just use an Internet DX spot list for160 or your band of choice?
Van, thanks for posting the FAAhandbook – yup, that is the site, other than this one has the VHFantennas on the doghouse. What would there use be? The top hat andthe Yagis are on a North South line, about 5 miles from the airport.
When I found the site, I was not eventhinking of ground radials, but there is a junction box on the sideof the site house and this place was in a clearing.
Why don't we see more of this kind ofantenna (with top hat wire or like on the FCC seal) in the amateurservice now days? I have seen old time pictures of these antennas. Is it the substantial cost of the copper with all the radials? WhenI read the FAA manual, I can't help but wonder if the major cost ofthe site is in all the copper cable!

I'm not Sigi, but I always recommend WWV for quick propagation beacon
uses, in this case 2.5 MHz. (2.5 kW vertically polarized)
Modern rigs, with memories, changing between the WWV channels is
frequently simply the rotation of a knob or press of a button.
(without changing antennas)

Here in West Central Florida I occasionally find no WWV transmissions
are detectable, just as most non-local HAM transmissions are not coming
through.

Still the most efficient way to load a vertical. Top loading with a capacity hat. Notice also that the number of radials is 16 only as long as the antenna. The fringing fields of the antenna will not benefit by longer radials extending beyond those fringing fields. And adding more radials will not buy you much. A maximized antenna system given cost, performance and lot size.

Cluster spot may help ...

A good beacon for 160 would be a mediumwave station on upper end (around
1.5-1.6 megs)

Yepp ... a good ground is expensive :-)

Why we do not see them more in ham radio(this antennas) ???

It is a vertical with tophat

And that is needed for ndb cause you can not build a few hundred metres high
antenna close to an airport (just tooo dangerous)

In our ham bands you would only see such antennas at the very longest
band(s) (500kc and 136 kc ... maybe on 160m also)

On all higher bands a tophat is not needed and would only lower radiation
resistance (and then the ground resistance takes a great amount of your rf
energy)

Efficient way ... yep that is

Look here

http://www.waniewski.de/MW/Bremen/bremen_mw_1en.htm

mediumwave antenna only 45m high

I scaled that down to topband ... added 2 more topload wires ... and what comes out??? Only 0.1 wl high antenna needed (for 160m IT IS AROUND 15m ONLY!)

And cause it is a folded radiator (like a half of a folded dipole) the radiation resistance is transformed up to about 4 times ... voila 50 ohms input without any tuning parts at feeding point

Jon:
Re: your question:

The VHF yagi at the COMLO site is for the outer
marker beaxon (OM) and when the pilot on final approach
flies over it, a panel light flashes to indicate
approximately that he is on a 5 mile final approach from
the end of the runway. Sometimes as well, the
system might also have a middle marker (MM) and possibly
a 1/2 mile final approach IM
(innermarker). Since the yagi is pointed straight up, it can be mounted right
on the Electronics building/shelter.

This is the URL for a Diagramatic view of the ILS
runway 28 Approach Procedure, with radio
facilities depicted as flown by a pilot.

Just click on this URL: http://155.178.201.160/d-tpp/1412/05257IL28.PDF

The FAA POURS money into its Aviation systems,
and uses only the finest materials (and lots of them)
in its aviation facilities. But they also have good designs to follow as well.

Just go with self fusing tape. After using it for a while, I am a total convert. No goo, no mess, no hour or so with solvents cleaning up coax seal on a PL-259 and a SO-239. I am currently on the lookout for some non-convertable C-Bander to donate the remaining stock of coax seal.

Self fusing tape is now universally available via QST ads, HRO, ($5.99) Gigaparts, ($3.99) Home Depot ($6.99) and I am sure other ham stores now stock it as well.....ten foot rolls....Home Depot has a video.

http://howto.homedepot.com/videos/watch/2900244146001/Nashua-Stretch-&-Seal-Self-Fusing-Silicone-Tape.html http://howto.homedepot.com/videos/watch/2900244146001/Nashua-Stretch-&-Seal-Self-Fusing-Silicone-Tape.html
If the self fusing tape gets a cut, it can rip under stress, so an overcoat of turn to goo black tape may make sense, although everything will still be clean and tidy underneath.

My intention was to try and keep moisture out and off of the connection
from the coax tail. I haven't had water in a connector in over 40 years.
I'll probably use a plastic garbage pail to keep the snow away the bottom.

Large diameter shrink tubing is available at most auto parts stores. The new tubing has adhesive on the inside, and once shrunk with a hot hair dryer, provides an impervious barrier.

That's not new. It's been around several decades (that I know of). Everyone sells it, not just auto parts stores. An actual heat gun with heatshrink attachment makes it shrink faster, with less possibility of damage to the wire/cable.

Large diameter shrink tubing is available at most auto parts stores. The new tubing has adhesive on the inside, and once shrunk with a hot hair dryer, provides an impervious barrier.

I used "Alpha type FIT" heat shrink tubing for over 20 years, in high
Voltage applications.

There we go! Problem solved. I first used shrink tubing in the 70,s when I was a pilot on water bomber aircraft. Great for keeping errant wires out of the way. It is however, being continuously improved, and the new stuff is truly awesome

This is second hand but my friend Jonathan, W6GX, in Colorado has the SAL-20 and he shared with me videos of it in use and I am totally impressed. I think it has made a tremendous difference in his low band DXing. At my previous QTH I used a K9AY receive loop and it made a huge difference for me especially on 160m.

Good luck in whatever you choose.

From: wt4t@...
Topic: 34804 Message: 34804

Have a new HT ,2 meter/200mhz. The radio works fine with the factory antenna,but would like to put a better antenna on the ht. Have a 220/901 HT ,changing from the factory to a diamond antenna really brought the radio to life. want to do the same for the 2/220.
I have looked ,googled etc , have not been able to find such antenna. the radio requires a SMA female connector,but could adapt to male.
any suggestions?
thanks

actually shipping out of England on eBay seems reasonable
ask Andy what a typical shipping out to say the west coast is like
I guess the problem is the size of the box = diameter of loop

I shipped a WWVB antenna from Boston to California some years ago
via UPS. IIRC, it cost almost $200 due to the size.

The Buyer was really motivated !!

I'll ask him.

34809. Cobweb monoband 15m

Yahoo group: ham-antennas (2014)
Date: 2014-11-22 22:40:39 UTC
From: Keith Heimbold
Topic: 34809 Message: 34809

I built a cobweb antenna monoband for 15m for about $20 using bamboo stakes and a kit I bought on eBay for the 1:4 balun. It works great. It doesn't weigh much and I am very happy with it. Just thought I would mention it as an easy project. I have been working a lot of DX and domestic stations with it today and I am very surprised. It shreds my G7FEK wire antenna in terms of performance.

I used a lot of info from this group to build it and my G7FEK.

I will have to check that out. It is also almost perfectly resonant on 17m but it doesn't seem to perform that great on that band. I am very surprised how good it is on 80m. I have been using it for JT65 and CW (where it is resonant). It is also pretty darn good higher in the band where it is closer to 4:1 swr. I have heard American Samoa and Japan pretty strong in the SSB DX window with it at 25' apex. Very good in my book.

Hi Frank,

I just looked on the web regarding his recommended changes. They look interesting and i am considering giving them an attempt. I do believe that I have a chance to influence the swr on 40m by shortening my current short leg a little more but that requires me to take the antenna down. I might do it over the long Thanksgiving weekend.

Looks like swr on 30m goes way up in his model. Mine is around 4:1 and I have been working some DX stations on it so I may not mess with trying to get 40m to tune better. Also 20m is off and performance is terrible so I may end up putting up that suspended wire that is recommended.

Thanks again & 73,

Keith

34816. small Yagi or hexbeam for dx phone

Yahoo group: ham-antennas (2014)
Date: 2014-11-24 17:18:51 UTC
From: goldenrosecottage@...
Topic: 34816 Message: 34816

I have used dipole antennas with JT65 to reach 50+ countries.

I would like something with more gain and directivity to help with DX phone.

I have a space that allows for an 11ft maximum radius antenna, 30 ft high.

A Mosely Mini-32 would fit, as would a DX Engineering hexbeam.

Does anyone have experience with these or other small antennas for DX phone?
I am in Colorado, and would like to reach Europe and Australia.

thanks,
Mike k0grc

Mosely make a fine product. They were in St. Louis county now in a small town right by me. The Mosely Mini-32-A only covers 3 bands, I would take a close look at a NA4RR hex beam, a fine product , covers 6 bands at a good price. I have one and love it.

From: Bill Blomgren (kk4qdz)
Topic: 34816 Message: 34818

The hex beams are about 10' radius (minimum) which means a 20' round circle to spin the antenna. (I have the k4kio hexbeam here..)
20' round is a biggie for "under a roof" -- but if you have the room it is a great antenna.. 20 thru 6..
 KK4QDZ - Now with Extra Class Priv's, and a tiny KX3 to enjoy them!

Mosely make a fine product. They were in St. Louis county now in a small town right by me. The Mosely Mini-32-A only covers 3 bands, I would take a close look at a NA4RR hex beam, a fine product , covers 6 bands at a good price. I have one and love it.

This sounds like a very good possibility. It has great reviews on eham, and might fit in my space. Are you able to do voice DX to Europe and/or Australia?

thanks again,
Mike k0grc

The k4kio also has incredible reviews on eham (118 @ 5.0/5.0) ! And the size might work.
Have you worked Europe or Australia on voice with the k4kio?
It might sound like a silly question, but I have only done DX with JT65 digital.
And when listening on voice, I only hear the US person on a DX contact.

thanks,
Mike k0grc

Mike,

I used to have a really awesome shack with towers and big Mosley antennas. IMHO, Mosleys are the best out there (nice design, robust, no moving parts) but for a small footprint nothing beats a hex beam. I have a portable one and it is great. In fact, yesterday I was fortunate enough to work VU4KV with 100W and a hex beam at 25' on 20m. If it wasn't for a portable hex beam I would never have worked that ATNO.

I have also owned a MA5B and it wasn't bad and is smaller than the hex beam. So if size gets even more constrained I would consider it as an option. It is better than a stationary dipole without a doubt.

Good luck!!

Keith

Sp7idx makes very good hex beams and performance wise are great. I would prefer the Hexham over a ma5b

Hi Keith,

I would be interested to know the results of any changes you make. I am interested in the modified G7FEK antenna for 30, 40 and 80 metres as I have limited space. I have a beam on the roof for the higher bands.

Hi Frank,

I will post my changes to the antenna including all dimensions, added elements etc. it is a surprisingly good performer on 80m. It is better on 30m at the moment versus 40m but is usable with internal tuner (TS590S) on both of those bands. I am hoping that shortening the smaller horizontal element and adding the wire for 20m will provide me better performance on both 40 and 20.

I decided not to pursue the changes that the other G8JNJ has recommended at the moment. For an antenna that cost less than $40 in materials I am very pleased with it.

Keith

I don't have the KIO hexbeam up right this instant, but I know that there are several people on the Elecraft net that use them and rave about them. There is a 3 element variant out of europe that does even better... effectively a 3 element yagi on 20 through 6 meters, but it is a tad larger.. (5-8 feet larger in its width - which put it in trees at my location.) However, there are comparisons on the web. (the extra 2-3 db of gain would be nice...) The results are very good. I'm in an apartment, so I have to do a push up pole that is "temporary" in nature... working on getting the needed bits and pieces for a push up pole with rope for guy work... and get the pole to the apartment. I haven't worked Europe or Australia with it.. but don't see any significant issues doing so once the propagation deities decide to smile... For rental/portable operations, which is my current situation my traffie hex pak antenna has been the perfect option. These aren't manufactured any longer but you can change bands in about 15 minutes. I have owned a K4KIO and with all the wires portable ops and the ups and downs would have been a huge undertaking in my portable situation. Of course not having to change bands would be cool. Currently I have it up for 20m, use my cobweb for 15m and my G7FEK for all other bands.

If you can get your hands on one of these Hex pak antennas I would recommend it.

I have a long run of CATV Hardline, (75 ohms) from my operating position to the top of the tower. This run is about 275 feet. At the top of the tower I have a quad for 432 and 144. There are separate feed lines for the driven elements. So, I need to convert the 75 ohm hardline to the 52 ohm driven element.

Has anyone use a modified MFJ-916BC for this task? In other words. Has anyone modified the MFJ Duplexer so that you can feed it with 75 ohm coax and still retain the 52 ohm dual output? It would seem to me that maybe spreading a coil or padding a cap could accomplish this. I have asked MFJ but they don't respond. I have contacted technical services at ARRL but they were no help at all.

Maybe someone here has solved this problem.

73,

Dan, W8KMX

Not the MFJ, per se, but any good filter book or calculator "can" use different impedance's on the ends. So a diplexer with low pass and high pass legs can do the job for the 144 and 432 antenna feeds.

I say, try it without making any impedance changes, the error isn't
that great.

From: goldenrosecottage@...
Topic: 34816 Message: 34832

Wow! Thanks for all the great information. I'm new to this group, and I really appreciate all the responses!

Originally, I sold my xyl on the "look" of the Mosely Mini-32-A (2 20ft elements, 6ft apart).
The hexbeams all put quite a bit more metal in the air, which is probably why they work so well.
Our Victorian (1879) house is fairly small, and I want to go with the smallest antenna that will allow for phone dx to Europe and/or Australia. Before I go with a hexbeam, I need to find out more about the small Yagi antennas.

I'll post a new question specifically about the Mosely Mini-32-A.

thanks,
Mike k0grc

34834. Dipole into a loop

Yahoo group: ham-antennas (2014)
Date: 2014-11-25 20:56:59 UTC
From: bartenderjim2002@...
Topic: 34834 Message: 34834

Hi to the group,

First I want to take this time to wish all in the group a Happy Thanksgiving (if you are in USA, if not then happy day) and Happy Holidays to all...

I have a question regarding changing a dipole into a loop...A number of years ago I built a homebrew 10M dipole. just some wire soldered to a piece of coax and attached to a light piece of wood for stability. I had this up in an inverted V form for a lot of years. But now---space availability has changed. What I would like to do is put this dipole onto a cross formed from PVC pipe, stuck onto a piece of PVC for a mast and be able to put it outside and then take it back in when I am done.

Questions---will the charactersistics of the antenna change? I used to do real well with this antenna on 10M have QSL's from 3 different countries when it was set up in between 2 apartment buildings...but now???? can't use this space any longer...so am thinking this might be the route I need to take. If this works then I will also do the same for my G5RV,jr....these are thoughts only just asking...trying to work out my restriction problems.

Thanks for all the help and information you guys have provided in the past and hopefully provide in the future

Jim, Changing the dipole to a loop will work fine. However, there are matching problems.
If you make it an open half wave loop it will be very low impedance feedpoint.
If a closed half wave loop it will be a high impedance.
If you add wire to make it a one wave loop it will be about 120 to 150 ohm feedpoint.

There is a similar antenna, cobweb antenna, that is a half wave loop on 5 bands.
It has about 10 ohms feed and a balun is used to bring it up to near 50 ohms.
You can GOOGLE Cobweb antenna to get information.
Other information about loops is in the ARRL Antenna Handbook.

From: Mel Farrer
Topic: 34834 Message: 34836

Actually it isn't difficult. Any dipole can be pulled into a square configuration. Impedance will change and needs to be addressed, but there are many examples of a dipole square along with loops and even one called the Hula Hoop. All of them are smaller in size physically than the regular dipole or inverted V. Bill Orr's last HF antenna handbook had a neat one allowing operation on two bands. page 5-8. Good luck.

One thing about what Ron says. With that much coax of a run, the loss might just smooth the match out. Remember it is only 1.5:1 direct!!!!! However, you still have to split the energy low band and high band with a diplexer.

The quick and easy way to get a good match on a mono-band loop is to add a 1/4wl 75ohm section of coax as a matching transformer. A loop is one of my favorite antennas, it is my only antenna for the lower bands, 40 thru 160. You can make a 2:1 balun for a monoband loop but a short section of coax is easy and quick to do, just remember to adjust the length according to the velocity factor of the coax you use and you will have great SWR.

Ken,

In over 45 years with many wire antennas, I've not noticed ANY difference between insulated and uninsulated wire. Using shrink wrap will make it cost more. For the strength, just use hard-drawn copper or copper-covered steel wire. I like the FlexWeave wire from Davis RF. The VERY high strand count maximizes the durability. You can get it in bare and PVC-coated.

From: Myron WVØH
Topic: 34828 Message: 34843

Well in one instance, yes, this is correct but at worst case, as noted in original post the mismatch could be at 112.5 Ω. But that is if your entire system rotates phase exactly to a half wave point, un masked by matched loss of the line. There is 275 feet of line here. The loss at VHF is going to be several dB, if this is 1/2" hardline, and 4-ish dB matched loss at UHF, this brings down the worst case mismatch probably closer to 1.5:1 at UHF and 1:9:1 at VHF. Mismatch loss and connector loss make (mask) the SWR lower.

Again, you all are right, I would try it first without adjustment. Then if needed, adjust the line lengths at the rig end. You may get lucky and land right on the zero ° point with 1:1.

I ran a Smith Chart model exacerbating the loss to show the coax spiral in to 75 Ω but it is neat to see the effect. I could only do a few phase wraps and not the entire 275' line. UHF would spiral in quicker.

Mark,

My point should have been obvious (disagreeing with your comment). To be specific, counter to your experience, FlexWeave wire is quite durable. Steve Davis (owner of Davis RF) told me it IS hard-drawn wire.

And, to qualify my testimony, New England isn't the only region that experiences severe weather. As well, we have some VERY severe storms in the Pacific Northwest. We just don't typically advertise it.

And, this will now be my last post on this subject:

I run a single common feed to 1/2 wave 80/160 dipoles and have had no luck with FlexWeave staying up in our New England winters. I was only getting about 6 months out of them. I changed back to hard drawn, and have had the present ones up for several years.

Ken,

In over 45 years with many wire antennas, I've not noticed ANY difference between insulated and uninsulated wire. Using shrink wrap will make it cost more. For the strength, just use hard-drawn copper or copper-covered steel wire. I like the FlexWeave wire from Davis RF. The VERY high strand count maximizes the durability. You can get it in bare and PVC-coated.

FWIW, I live in a very windy area in Northern Ca near the coast and have had the best results from Flexweave myself.
It holds up better than any other antenna wire I have used, and I have tried them all in my 55 years of being a ham.
Oops revealing how old I am. hihi

Fine, in my experience (45 years licensed as well), with several dipoles put up on the tower by KC1XX and crew, the FlexWeave under-performed plain old 14g multistrand wire. The FlexWeave dipoles consistently came down, torn - weave pulled apart, whereas cheap 'hamfest' wire stayed up.

Personally I will not waste any more money on FlexWeave, period.

I made no uncalled for derogatory comments about weather or east coast vs west coast.

It is interesting that the flexweave performs quite well for some and not others in similar windy conditions.
The variable then that we should compare is how the antenna wire is attached to the center insulator and the end insulators.
Is the connection designed to reduce the stress at the attachment points ? There are a number of ways to make this connection
relatively stress free and almost immune to wire damage from fatigue. Any wire will fail prematurely if not attached in a way to minimize stress,
even steel copper clad wire. Ask me how I know this, hihi.
My point here is that we should look at the complete system before blaming the antenna wire.
I think we have beat this subject to death now and should end the discussion.

In my experience, all failures occurred well away from the connection points. Installations were all performed by XX Towers, a professional team led by KC1XX.

From: Ham Radio
Topic: 34809 Message: 34851

Frank,

I have an update. I was able to sneak home early today from work and start on the antenna mods. I added the 20m wire as recommended and shortened the shorter leg by about 12” to fix my issue on 40m.

I hooked my rig expert AA-54 antenna analyzer and everything was out of whack.

I have been using the 1:1 balun from an old system I had as a connector to the system. I realize this is a non traditional approach to this antenna but I decided to use it. I thought it might be a good idea to have one at the feedpoint.

So after the mods I decided to connect the antenna through a 4:1 balun I had lying around and lo and behold 40m is less than 1:1 lower part of the band, 30m is just less than 2:1 (better than before) and 15m is 1.5:1 in phone part of band.

So if I swap baluns I get all the bands. I am going to play with adding more elevated radials and will report on progress. Right now I am making JT65 contacts on 15m. Before this experiment I didn’t hear much of anything on 15m with this antenna. So at the end of the day, I have a significantly modified version of the G7FEK. This antenna didn’t cost much and allowed me to unload an expensive commercial vertical that was a potential danger to my little boy who is always doing crazy stuff. He can’t do much to the wire antenna that could hurt him.

Hi Keith,

I would be interested to know the results of any changes you make. I am interested in the modified G7FEK antenna for 30, 40 and 80 metres as I have limited space. I have a beam on the roof for the higher bands.

73, Frank, VE7AWV

Hi Frank,

I just looked on the web regarding his recommended changes. They look interesting and i am considering giving them an attempt. I do believe that I have a chance to influence the swr on 40m by shortening my current short leg a little more but that requires me to take the

antenna down. I might do it over the long Thanksgiving weekend.

Looks like swr on 30m goes way up in his model. Mine is around 4:1 and I have been working some DX stations on it so I may not mess with trying to get 40m to tune better. Also 20m is off and performance is terrible so I may end up putting up that suspended wire that is recommended.

Thanks again & 73,

Keith

I built a cobweb antenna monoband for 15m for about $20 using bamboo stakes and a kit I bought on eBay for the 1:4 balun. It works great. It doesn't weigh much and I am very happy with it. Just thought I would mention it as an easy project. I have been working a lot of DX and domestic stations with it today and I am very surprised. It shreds my G7FEK wire antenna in terms of performance.

I used a lot of info from this group to build it and my G7FEK.

Thanks & 73,

Hi Keith,

Well, what a surprise, I did not think a balun was needed for this antenna! That is the beauty of experimentation, I like the surprises when things work out. Keep going with the mods, the results will be interesting to see, especially with the elevated radial.

I have just enough room to put a G7FEK antenna just outside the shack but I will have to put up a couple of masts. Then I can put the elevated radial on top of the wooden fence. Hmmm, I should think about the opposite side of the yard and use the chain link fence as a radial. Now that is a thought.

HI Brian,

Can you provide details regarding the capacity hat you use for 160m.

Thanks
Don

My 80m cage inv vee / 160m top-hat vertical has been up over a dozen years through MANY severe storms that pass thru Western Washington. Many on the 'right coast' don't know they're not the only ones who get severe weather. We typically don't advertise it.

I run a single common feed to 1/2 wave 80/160 dipoles and have had no luck with FlexWeave staying up in our New England winters. I was only getting about 6 months out of them. I changed back to hard drawn, and have had the present ones up for several years.

Ken,

In over 45 years with many wire antennas, I've not noticed ANY difference between insulated and uninsulated wire. Using shrink wrap will make it cost more. For the strength, just use

hard-drawn copper or copper-covered steel wire. I like the FlexWeave wire from Davis RF. The VERY high strand count maximizes the durability. You can get it in bare and PVC-coated.

34855. 40m cobweb dimensions

Yahoo group: ham-antennas (2014)
Date: 2014-11-28 19:17:49 UTC
From: Keith Heimbold
Topic: 34855 Message: 34855

Just a quick question. I was wondering if anyone has references for a 40m cobweb antenna. I was wondering what the dimensions would be. I have been super happy with the 15m monoband cobweb. It was a fun project for sure and it works amazingly well. Thought a 40m version would be fun to build when I am at my inlaws this Christmas holiday.

Thanks,

Keith

A half wave 40 meter loop will be the size of a 20 meter quad loop, about
17 feet on each side and 25 to 26 foot across the diagonal.
That will make it 68 foot circumference. You may have to add or subtract a
bit to resonate the loop.

34859. Lightning mitigation for window line feeder.

Yahoo group: ham-antennas (2014)
Date: 2014-11-28 20:40:11 UTC
From: rhulett1@...
Topic: 34859 Message: 34859

I am planning a 40M horizontal loop fed with window line to be used for multiple bands, and want to minimize the amount of coax used. In fact, would like to eliminate it entirely, and use the balun inside the tuner. The house safety ground is about 25' from the operating position. Was thinking of mounting two polyphasers on the safety rod, then connect center conductor of coax connectors to each leg of window line. This will be fairly expensive though.

I've seen an arrestor designed for window line, but it's construction looks fairly complex with a lot of parts mounted inside a plastic box, it wasn't cheap either.

What strategy are folks using to provide lightning mitigation (yes, I know a direct or close strike will cause damage anyway) for window and open feed?

Thanks in advance and 73, Curt KB5JO

I’ve been wondering that myself. Of course, that is an advantage of the direct coax fed loop is that it is grounded on one side. At one point I had three open wire feeds plus the window line fed loop coming in and I was working on a board with 6” surplus knife switches for grounding. Since then I’ve been migrating back to coax.

The spark plugs that Mel mentioned are a good idea except they still leave a large static buildup on the line before they fire and I also worry about them arcing over under certain transmit conditions.

I used a spark plug when was a kid back in the 60s. Maybe that is how will deal with this issue. The price is better than nearly $100 for two polyphasers. Hard to imagine there's been so little progress in 50 years.

I think that one solution is to put a 1 Meg resistor across the spark gap. That will drain the static on slow ramp stuff but not the big induction spike, thats the spark gap's job.

Hi Curt,

The best and least expensive solution to lightning protection on open feed or window line is a simple spark gap to ground on each conductor. A bleeder resistor can be added between the window line and ground on the spark gap protection device to chase common mode current, but I generally find that unnecessary.

The simplest solution is what we used as kids, spark plugs, only now days we have PVC pipe in which we can seal the spark plugs in to avoid spiders and other insects from bridging the gap and creating signal losses.

I generally create a drip loop a couple feed away from the side of the house and install my spark gap devices there, so any strikes go to the ground rods and do not blow siding away. I did blow the siding off my parents' home when I was a kid back in the 50's, and after many hours of repairs and painting I did the loop and ground away from the house, had many more strikes but no more damage.

Randy

OK FOLKS:

Here are the rules of the reflector : HAM-ANTENNAS
This file will be sent once a month automatically to remind all users.

1. Name calling (race, religion, politics, gender, etc.), is prohibited.
2. Telling someone they are ignorant (in any way, shape, or form), is prohibited.
3. Denigrating other races or minorities, or expressing POLITICAL VIEWS will earn you moderation or banning.
4. If you do it privately it is a private dispute. When/if it spills over onto the reflector, you will be moderated or banned.
5. Even coming close to these boundaries is to be avoided.
6. Banning/moderation will be used, with NO notification to the transgressor.
7. Civil chatter and Civil wordage is THE rule.
8. IF the Moderators are offended, then penalties will be applied.
9. There are two Moderators, EITHER can ban/moderate you.
10. Moderators ARE the final arbitrator of disputes, we hate bickering!

34874. do I need a coil ?

Yahoo group: ham-antennas (2014)

From: tivoligardens@...
Topic: 34874 Message: 34874

Good Evening all

I have purchased 2 MFJ-1979 (16.9' each) telescopic whips for use with my KX3 which has an antenna tuner as a dipole. I can also configure my antenna as a vertical using 1 whip.

Should I build a couple of coils for the lower bands or will I be just as effective with what I have ?

Thank you for your advice in advance
Hal w4hal

At 16.9 foot long at maximum extension, anything UNDER 30 meters "should" have coil, but the tuner could handle 30 M. But 40 & 60..and for SURE 80 & 160 will need a loading coil. On 160, 16.9 ft, even with the HUGE coil you would need is a waste of time! At the most...only 5% of the power would be radiated into the air. And I am being VERY generous with that estimate. Maybe 20% tops on 80. This is all based on you stating that you will only have 16.9 foot...going up!
There is no escaping the law of effective radiating antenna length on 80 & 160.
Good Luck! (The KX3 IS a fine radio!)
73,
Dave-KJ4PF

David

Thank you for your quick reply. If I do a vertical its 16.9 with a dipole aka 2 whips link a buddypole it double.

Can you point me to plans for making my own multiband coil ?

Hal

Get you a large coil and a good alligater clip and start sampling each
turn of the coil and watch the results . Log the results for the future

I use the MFJ-1979 on a Tarheel screwdriver antenna.I have it in my yard with a bunch of ground radials.I leave it about 15.8ft for best SWR on 20m.
At its maximum coil setting I can pick up 160m. I need at least 5W from my IC-7000, and have reached around the US and into Canada on JT65-HF. I mostly do digital, and switch antennas to the Tarheel for 80m and 160m when 40m gets too noisy or crowded. Its not the most efficient setup for 160m, but it is fun for grabbing a few contacts.

Hi Hal,

You will will find hundreds of plans for building RF coils if you Google the subject. Keep in mind that they are simple and no single design fits all.

The best solution is to score some heavy copper or aluminum, such as the solid wire used as main panel grounds in our homes, and a form (I use 4" PVC pipe), and begin winding. Lighter wire works, but is not so durable in the weather. Build yourself a coil about a foot long tightly wound on the form, once wrapped remove it from the form, then figure on stretching it so there is around a wire's width of space between each wrap as a starting point, and use a jumper and alligator clips to short the coil as you test different frequencies. The electrical length can be adjusted by a combination of stretching the coil to obtain different spacing and through the use of jumpers, and it can be quite an experience finding the sweet spots for your particular application.

One of the issues to remember is that VSWR has no real relationship to your ability to transmit if the electrical length and elevation of your antenna system is inadequate for the bands which you intend to work. I have seen many physically short close ground mounted verticals that obtain low VSWR results, but do not transmit for beans because they violate the laws of physics relative to the bands being sought. So an analyzer gets you in the ballpark, but physics keeps the short antenna from achieving the desired results.

There are many authoritative references on physical length and elevation of antennas relative to ground reflection also available the use of Google. The ARRL Antenna Book is another readily available reference that is handy to keep around too.

Yet, nothing beats experimenting and determining what will work in your situation.

I am in the process of mounting a 102” stainless steel whip with a manually variable coil beneath it. If the coil manufacturer is to be believed no antenna tuner is required after ‘tuning” the coil for the desired band. The brand “Wolf River Coils” looks to be first class in structure. I will be mounting the antenna in the near future for testing. But the tuner looks to be a good alternative if you change bands often.

It is worth a read on the ARRL Mobile Handbook on matching the shortened 102" whip. Either a tuner, like discussed, or a matching coil or cap is required to deliver a reasonable amount of the power to the coil + whip arrangement.

I use a 102" whip mounted on the rear of the car with an Icom 706 and an LDG tuner mounted about 8" from the antenna feed point on the inside of the trunk lid. Works great on 10 thru 40, work into Europe regularly and have work New Zealand on 15m with 100 watts from E.MA. 80 does tune ok but for local stuff.

One does not connect to anything, the other connects to ground. You take a wire with some type of clip and go from the antenna to some point on the coil to match. For example. If you want 20 meters, you would find the resonance point on the coil that matches at 20 meters, and that is where you would place the clip. Say you later wanted to move to 40 meters, you would find the resonance point for 40, then place the clip at that point.

John

Thank you for the quick reply

so if I understand correctly if I have lets say for ease of discussion I have a MFJ-342T and a MFJ 1979.

I connect my feed line to the mfj-342t then I connect my coil which has the bottom end of the coil connected to that point. I then attach the antenna to the top of the physical tube of the coil and at that point I connect a wire with a clip. The end of the coil nearest the antenna is trucked in side the tube.

Regards and thank you for your be patient
Hal

I'm not familiar enough with the gear your using to give you the best advice on how to set it up but, I can tell you what I have tried and what worked. I have an Alinco DX70 mounted in my old Ford E250 van. The radio is mounted up front on the engine cover. I am using an Alinco auto tuner mounted about 3 inches from the feed point of the 102 inch whip. at first I used a 4 inch piece of wire to connect the auto tuner to the feed point but that caused feedback when transmitting. After a little trail and error I found that I needed to use a 4inch piece of RG8 coax with the braid grounded at the feed point and the auto tuner. No big surprise there.

What I found that was a bit of a surprise was that not all metal panels provide a good RF ground even if they are a good DC ground. I had to try a few different places for the ground before It started to work as I expected. The mounting ring for the antenna mount was a good place to start. A field strength meter was a useful tool inside the van to see how effective the grounding was. Poor ground equaled more RF inside the van. Also remember that if the whip can contact any part of the body when moving you need to insulate the antenna so that it doesn't contact the body. I cut a slot in an old tennis ball, slid it on the antenna and used silicone caulk to keep in place at the point where is could hit the body to prevent it shorting while moving.

It works extremely well on 20 through 10 and pretty dang good on 40. I've had people express surprise that I was mobile given the strength of my signal. One of my favorite contacts was in summer of 2013 when I has talking to a pair of mobile stations on 20 meters in the Liverpool area of England. I hope this helps and good DX to you.

The original article was: N4PC Loop (CQ, Dec. 1990) All of the wires were connected. The pattern produced a null in the vertical plane on the ham bands. 80 M the pattern is omni. multi lobes on higher ones. I have modeled it and had one up in the 90's. Good quiet antenna but required careful matching and a tuner.

I built this last year and used it at field day. It works really well. I put a 24 awg insulated wire inside a crappy pole and use ropes with tent stakes to set it up. I can put it up in less then a minute. OBTH at least 20 feet of coax is required to make it all work.

I,m glad it worked well for you. I noticed in the article from the Hawaii group, that the wire can be up to 60 ft or more feet in length. Although the wire length is not terribly critical, there are some websites that discuss ideal, and not so ideal random wire lengths.

This antenna is fun to play and experiment with!!....and that is what it is all about!

I use a 102” whip mounted on the rear of the car with an Icom 706 and an LDG tuner mounted about 8” from the antenna feed point on the inside of the trunk lid. Works great on 10 thru 40, work into Europe regularly and have work New Zealand on 15m with 100 watts from E.MA. 80 does tune ok but for local stuff.

34898. Antenna Tuner for a Random Wire Balcony Antenna

Yahoo group: ham-antennas (2014)
Date: 2014-12-08 22:16:22 UTC
From: ve7rvs@...
Topic: 34898 Message: 34898

I have a counterpoised 30 ft balcony endfed antenna (live in an apartment) tied to a 9:1 balun with about an 80 ft of coax to an LDG IT-100 tuner connected to my Icom IC-7200. On sunny days my SWR is reasonable manily for the band I cut my counterpoise for, but once my concrete deck and its walls gets wet (too much coupling with my counterpoise?), SWR characteristics change and my tuner is already satisfied with about about 1.5:1. This is probably good enough, but I would prefer a better matching on the radio side, as I operate digital modes (JT and WSPR) with key downs of about a minute or even more.
I am thinking getting a tuner and prefer a Palstar AT-500 but also considering an MFJ-949E due to its much lower cost.
Does anyone have any experience using a 949E for such a compromise antenna and how useful it is for such?
TIA,
Ramon ve7rvs

Read the reviews of each and the SGC series, before paying good money..... Like one said, look at the auto tuners also, particularly if you are not going to run high power, they are pretty reasonable.

Sure can, I had my tuner originally mounted at the rig and it did work, just performed a bit better at the antenna feed point. Go with what you can make work. The LDG tuners will tune most anything.

Hi Joe,

The coax trick yields a characteristic impedance twice that of one coax, so using two 75-Ω pieces gives you 150-Ω, and so on (I think that's right). But, the mismatch loss caused by this coax will reduce the power applied to the antenna, so you will loose the benefit of that balanced coax trick.

I would consider using two pieces of ready-rod or all thread rod to bring the balanced wire inside. Drilling two small holes through the wall of the house are very easily concealed if you leave.

Another thing, characteristic impedance is only a factor after a phase length greater than 10-30 deg phase length. So 6" of ready rod will not even register any impedance at HF because it's so short relative to its wavelength. So the transition through the walls could be made with the two rods an inch or two apart.

Two pieces of RG-59, RG-6 or RG-11 = 150 Ohms
Two pieces of RG-8, RG-8X or RG-8 = 100 Ohms, I would recommend a 9:1
balun outside fed with The same coax currently used.

If the two sections are short, the losses would be unmeasurable.
The higher the impedance the lower the loss.

Not necessarily a suggestion here, but a question - what's the harm in using coax from the transmitter to the outside of the wall then using a 6:1 or 9:1 xmit line transformer (balun) to transition back to the open line feeder?

Does that just not work, does it have high loss therefore isn't desirable, ... ?

Trying to learn a little here as well!

We frequently re-glaze a window pane with one plastic (Plexiglas or
Lexan) sheet, then and we drill holes in the new plastic panes and mount
headless bolts with two nuts on each end in each hole. (with washers)
(6-32 or 10-32 bolts & nuts)

Since there isn't a set frequency and loop length, one cannot guarantee 450 Ω resistive at the output of the balun. Baluns like a matched condition to be happy.

FWIW I feed an 88' doublet using RS 300 twin lead. Originally used that while waiting for some ladder line to arrive, but the twin lead worked so well never changed. The twin lead comes through the wall and attaches to a B1000 balun on the back of the Drake MN-4C tuner. Work all bands 40-10, WAS & DXCC, mostly QRP. I know several other ops using the same arrangement with great results. Worked Finland, Italy, Spain and Morocco with 800mW on 20M during the CQ WW weekend.

So, I would suspect feeding a loop with open line, window line, or twinlead would work well. I'm planning a 40M loop fed with twin lead from a 1:1 current balun mounted about 10' from the tuner on an outside wall. The less coax the better.

I suspect that if you run much more than 100W, delete everything said. Most my radios will put out is about 120W.

As far as I'm concerned, the most efficient HF "all band", city-lot-sized antenna is an inverted-Vee, with the legs as long as possible, and the center as high as possible, fed with open-wire-line from a balanced antenna coupler.

YMMV.

Ken,I hate it when the cadre don't take time to read the amateur history books.. Open wire antennas and ladder line were the thing we, at least me, started with. Watch the RF amp meter on the ladder line feeds and rock the tuning to get the current equal and match load for max RF amps. It was simple and worked on all band, HF of course. But then, that was on another planet called home.

I would run low loss coax from "the shack" to the window and put the
balun there, and I would use banana plugs and jacks between the balun
(as one set of the inside nuts) and the window so it could be
disconnected from the open wire feedline (and put the balun on a shelf
or a hook) when not in use for lightning protection.

Have you considered using a current balun just outside the basement and then run coax to the operating position. That wouldn't be a long run. I saw that idea in the booklet from the Wireman.Dave

From: jc_2aussie
Topic: 34898 Message: 34919

I use a home brew non resonate loop antenna , with home made open wire feeder to a balun at the house , then 5 ft of coax to anMFJ 941D manual tuner .
Inam located on the east coast of Australia , and with an F call lic can only use 10 watts , on 80,40, 15, and 10 mt bands , with this antenna system , Imhave had contacts into Oregon.
Loops do work and they dont have to be expensive, mine is made from reclaimed wire from an extension lead, and the open wire feed from heavey guage speaker wire
Just my experience from down under.

Cheers
Jeff

Are the ceilings "hollow" (isolated with some air) ... maybe you can route
the ladderline there?!?

Just as another idea

Look also the cg3000 (seems to be something like an sgc clone) ...

A friend from me uses that tuner on any band from 10-160 ... and he says it works superb

I was down in his shack only once and dont remember really off the top
of my head, will have to take a look and see what I can come up with.

I had in the late 70's something I wonder what in this type of use it
would be like, but I had some shielded 300 ohm TV twin lead. it was
larger that normal 300 ohm twin lead. probably 1 inch wide and 1/2 inch
thick. Inside was a typical 300 ohm line surrounded by a foam
dielectric, in a flattened oval shape this is where the outer foil
shield was so it had an equidistant distance from the twin lead inside.
and it had a wire so you can make the connection to the foil shield. The
system was made so you could run it anywhere just like coax, tape it to
tower legs,, run it through conduit etc.

I wonder if they even make anything like that and what the losses were
like with low SWR and High too?

And you don't have to keep a lot of distance away from metal. 5 or 6 inches away is enough from window line is all that is necessary.

Joe,

I haven't seen shielded twin lead but from an engineering stand point, there wouldn't be much difference between this or using two coax balanced line since you are confining the EM fields to a dielectric. The dielectric loss is a first order effect when you confine the fields, it is a second order effect with ladder line or window line because the fields are mainly in air, a much lower loss medium than foam or other such dielectric.

So consequently when the fields are confined to a dielectric other than air the loss goes up and the mismatch loss will rise when a mismatched condition is seen. But again, if you run a loop on one band and tune the loop for a single frequency and match the feed point impedance with the characteristic impedance of the transmission line you will experience the least loss. It's when you deviate from that condition by moving to another band and cause the feed point impedance to change is when the mismatched condition will exist and the mismatch loss will exist on the line confined by a shield, either coax or balanced.

Yah the tuner I have has to be within one foot of the radio so unless I mount them on the door of my Vue’s hatch It can’t be close to it. I don’t think my spouse will let me do that as it’s the family car. The side of the car is plastic so no joy mounting an antenna there. Now when we look at cars we make sure that a radio will mount in it.

Sure can, I had my tuner originally mounted at the rig and it did work, just performed a bit better at the antenna feed point. Go with what you can make work. The LDG tuners will tune most anything.

I use a 102” whip mounted on the rear of the car with an Icom 706 and an LDG tuner mounted about 8” from the antenna feed point on the inside of the trunk lid. Works great on 10 thru 40, work into Europe regularly and have work New Zealand on 15m with 100 watts from E.MA. 80 does tune ok but for local stuff.

Do you have a spare tire mounting at the backside of the car (seen on suv and such)

What about roof mount?? Some ski holders and you have a nice basement for antenna(s)

What car??? (I will take a look on it and see what could be done)

Thanks Sigi,

I have a 2005 Saturn Vue. Its not the Redline and I have a receiver hitch on it. The K-400-3/8C mount is about 3” under the glass on the hatch. I never did get the roof mounts and Saturn’s are no longer in production.

Tomorrow I can look at the car but getting around is a problem for awhile.

Dean,

Does the frame undercarriage have a round or square cross tube for the trailer receiver? I have made/welded up several that required a double offset to clear the fender skirt. I then made a right angle vertical column to a height the ham wanted welded a 3/8" plate with a drilled and tapped 3/8-24 thread for the insulating mount. Got pictures if you have the open ended cross member.....

It does take a bit of planning and work. Mine is in a Ford Fusion (company car), I can drill holes and mount stuff within reason. I have the control cable extended and the tuner is mounted on the inside of the trunk lid. My antenna mount is home brew which fits behind the license plate, the tuner is right on the other side.

Before this idea I did have the tuner mounted with the main part of the 706 under the seat and it did work OK. If that’s what you can do, go for it. You’ll make contacts.

You must select a car that is radio friendly, Hi Hi

I use a 400 foot horizontal loop up about 40 feet and fed with 450 ohm ladder line. From the feed point, the ladder line goes to a 4:1 current balun. Out of the balun there's about 6 feet of RG213 to a remote auto tuner. Then about 100 feet of RG213 from the auto tuner to the shack. The remote tuner and balun are strapped to one of the trees which support the loop. Bringing the ladder line all the way to the shack was not an option for me. This solution adds to the cost of the antenna, but its still very inexpensive especially given the versatility it provides. Also, feeline loss is minimized as the tuner is located out at the antenna. Once the tuner finds a match, that 100 foot run of coax sees 50 ohms present at each end.

Yah the tuner I have has to be within one foot of the radio so unless I mount them on the door of my Vue’s hatch It can’t be close to it. I don’t think my spouse will let me do that as it’s the family car. The side of the car is plastic so no joy mounting an antenna there. Now when we look at cars we make sure that a radio will mount in it.

Sure can, I had my tuner originally mounted at the rig and it did work, just performed a bit better at the antenna feed point. Go with what you can make work. The LDG tuners will tune most anything.

I use a 102” whip mounted on the rear of the car with an Icom 706 and an LDG tuner mounted about 8” from the antenna feed point on the inside of the trunk lid. Works great on 10 thru 40, work into Europe regularly and have work New Zealand on 15m with 100 watts from E.MA. 80 does tune ok but for local stuff.

I have the manual MFJ945E and have used it on random wires, end fed verticals, multiband dipoles and now on a coaxial screen halo type loft loop on coax feed with a toroid 1:1 choke and its always been great for me, just remember to tune with the power down low and increase once a good match has been achieved which it always will be as its so versatile for the low price, although if your going to be using power levels 100w and under there are some great little auto tuners out there for the same price.
good luck with your choice.

I took a short cut for my HF antennas. Using a Harbor Freight bike rack, I turned it 90 degrees and drilled a new pin hole. Removed the structure for the two bikes an welded a piece of 1/4" steel on the end. Cut it to a 4" circle, drilled it for a ball mount and enclosed the bottom wt. a 4" black plastic sewer cap. The cap is held on by the 3 ball mount bolts, bolt couplings and short bolts. The ball is at the rear drivers corner topped by a 3/8" quick coupling. 54" Hustler mast and an other quick coupling. I have a Hustler 3 corner mount wt. a 10, 15 & 20 meter loading coils. A 2nd 3 corner mount has 12, 17 & 40 meter coils. It is always out of the way of the hatch. (2012 GMC Terrain) Easy to remove for the utility trailer.

Do you James, or anyone else, use a spring at the base of your whip assembly? I have just purchased a Kenwood 480 HX mobile and have a whip with a large Adjustable coil and a ball mount for my old pick up truck, all new. This is a 102” whip. Just considering whether the spring would be a help or not.

I will try to get a shot in the morning. It has been back there since 5/12. Can always see it in the rear view mirror. The three corner mount get a lot of attention. In addition there is a 2 / 440 antenna on the roof rack.
When ask about the antennas, I explain the three corner one is to contact the "mother ship" & the other one for local contacts. 8O)= I actually end up handing out a number of my ham cards to people interested in being a ham. One guy spotted me parked at Sam's Club, then later at a post office 10 miles away. He ask about becoming a ham.
BTW, the quick couplers allow removing the mast and loading coils when parked in a questionable area.

The spring is for the antenna to wobble around when it hits something. If you look, it has a braided jumper inside to keep the spring from becoming part of the circuit. A coil is a good idea at the bottom to allow for resonating the whip.

BTW, those 102" whips are tuned for the middle of the 11 meter band (CB), and when I was a young man they were called "Redneck Whips" because they were used by country boys trying to "get out".

I only use a 1" x 4" spring at the top under the coupler and the loading coils. The mass of the mast and loading coils offer a lot of torque at the ball. The mast is close to roof height and the small spring has protected the coils so far. I wouldn't leave the 40 coil up there waving around.

Thanks fellas for talking about mounting the antenna differently but I'm not looking to spend anymore $$ on the project. I have a nice K400-3/8" mount and the antenna will work with it nicely. The wife told me where she wants me to place the tuner at and the radio. It should work just fine. It will be awhile before I get it moved to the new location as I have to shed the walker first.

Thanks for all the replies they were helpful.

Years ago in my mobile setup i used a "mil-whip" (copperclad steel tubing)
... and on every "humvee" or tank you find a heavy spring at the base

I also mounted my whip with that spring ... and it helped A LOT!!

You could bend the antenna completely over and nothing happens to the whip

So ... yes such a spring helps (for robustness)

Subject: AW: [ham-antennas] Re: 102" whip mobile

Years ago in my mobile setup i used a "mil-whip" (copperclad steel tubing)
... and on every "humvee" or tank you find a heavy spring at the base

I also mounted my whip with that spring ... and it helped A LOT!!

You could bend the antenna completely over and nothing happens to the whip

So ... yes such a spring helps (for robustness)

Yes, the regular steel will rust faster than the stainless steel.

Normal steel will rust ... but the mil whips are copperclad with additional painting on top to prevent the tubes from rusting

34954. Antenna mast source?

Yahoo group: ham-antennas (2014)
Date: 2014-12-12 19:07:45 UTC
From: cabispop@...
Topic: 34954 Message: 34954

Need a 30 foot or so mast for my G5RV antenna. Unfortunately, every place I see on the net wants 7 times the cost of mast for shipping. Any ideas would be welcome. (By the way, I have 2 top rails from a cyclone fence up now, but the winds in my area have bent it.)

HOME DEPOT carries them,
ChannelMaster, Telescoping I think also different lengths,
and you can send to store and pick them up or ship to your home.

Do a google search "home depot telescoping tv mast"

I am very happy with the most I put together using aluminum tool handles purchased from Home Depot. They are each about 5 feet long and are made to connect to one another.

You will find them with the concrete tools. I paid $7 for mine, but the price has gone up.

I would get the black or gray pipe instead of the white pipe. The white pipe will get brittle after a while.

Why not a spiderbeam mast?

http://www.spiderbeam.us

$120 for a 12m fiberglass mast.

K6LK in Clear Lake has some VERY strong sections of military carbon fiber mast he is trying to sell. He is good in QRZ. I have 54 feet of it up and it took the 124 mph winds we had yesterday and laughed.

Dennis,

I’d try to stay with non-conductive mast material. You might consider using a windsurfing tapered fiberglass mast. I use one at my QTH. They are 18-20 feet long, hollow but quite sturdy. I get the extra length I need by inserting a couple military surplus fiberglass tubes in the bottom. Just a thought…

Dennis go to the photo section and look at the green mast sections. These are the ones Bill K6LK is selling. Easy to put together is 4 foot sections and rock solid.

A small 30ft system is no problem. Here is a sketch of mine, it is now used as a support for my copper slim jim. I also have a simpler 40ft tilt in my album. Small tilt is at
http://i1102.photobucket.com/albums/g453/KD0ZZ/Tilt2.jpg
Larger 40ft tilt at
http://i1102.photobucket.com/albums/g453/KD0ZZ/TiltOverB.jpg
My Kd0zz album in photobucket has more pictures of the installations .
Every small town has a steel shop or two where you can get the pipe.

Rich, KdØzz

Hi Dennis,

I just built a 34' mast out of 2, 1.5, 1.25 and 1" 10' sections of EMT that I got at Lowe's. I took a 4" pc of 1.5" pvc and quartered it after removing about 1/32" all around and attached them to the 1.5" emt to take up the space. I ended up with 34' because I used 24" overlap. The total cost was less than $60 which included some misc. hardware.

EMT, and any other conduit, is meant to bend. If winds bent his fence top rail mast, conduit sure won't hold up either.

Military camouflage net (tent) poles

They can be bough used for a few bucks

I can get those poles here for 2.5 euros each ... so for 30 feet I need just 20 euros (8 pieces with around 4 feet each equals 32 feet)

But these poles are somewhat flimsy if you go higher as that ... (a bit wobbling) so you need some guy wires for bigger height

Is there any reason you can't do some Rohn 26G or equivalent? You can often find it super cheap used, but even new 30' isn't that expensive at $120 per stick. Every now and again around where I live, an XYL of a SK will let you take it for free if you'll simply take it down. I'll bet at 30' it won't even need guyed with the proper concrete on the base when you are only hanging a dipole on it. Then you'd be open to putting up a heavier dipole arrangement like a nice fan dipole that is truly resonant everywhere.

Just an idea for improving for the future, if you are allowed to do it where you live, which is the problem for many. I hope it isn't for you.

All those postings are terrific, here's another:
Go to Cheapham.com and look under closeouts, their 43' will be available
this month at $125. It's a fiberglass telescoping mast that I believe has a radiator inside already.

This is what, if I understood correctly, the original poster wanted to buy but was put off by the shipping costs. I think he's looking at it wrong.

I bought a bag of these fiberglass poles - 36' total, I think - for like $7 on eBay, but they cost $20 to ship. Still, $27 delivered to my door.

The alternatives mentioned will all cost more than that and they are not delivered.

Having tried it 8-(, I know you can't raise 30' of EMT or water pipe or PVC pipe in one piece - it will snap or bend under its own weight. The tent poles (or a telescoping mast) can be raised in chunks.

I support a K9AY on the aforementioned tent poles. I was able to raise it alone and it is guyed with some parachute cord and tent stakes driven into the lawn, It has survived several winters where we regularly get winds of 100km/H. I've lost two flag poles (snapped/bent) and a BBQ grill that blew off the deck before I got a chance to build the railings, but the tent poles have weathered all.

Topic: 34954 Message: 34977

Here they cost 36 euro in a bag of 10 included postage ... but the ebayseller where I found thenm is just 30-40 miles from me so I could pick them up direct from him (2.5 instead of 3.6 euro each) ... if you just need 10 ... then let them be delivered to your door (driving with the car 30 miles plus your time ... go figure) ...

I drove there with a ham-friend ... we bought 100 of them ... and so it was cheaper to pick them up

But for indoor use, isn't a roofing filter required? Consider the extra expense before you act impulsively.

Window line is only used if you route the feedingline trough a window (hence the name) ... and roofing filter is only for antennas above the roof (hence its name) and not for indoor antennas

... don☐t forget to drop some snake oil on your rettysnitch :-)

Sometimes available from the same surplus vendors are the identical
product except made of aluminum. They can fit with the fiberglass ones.
This can lead to cleverness[*]. I suppose in Europa they are made of
aluminium instead, which has similar electrical properties.

A standard North American size of PVC plumbing pipe fits tightly over the
male end of the pole. (Too tightly, but a heatgun can encourage it.)
These can be used as insulators with the aluminum ones, or to provide
a convenient weak place for the mast/antenna to crack later.

[*] or madness. I sometimes muse about a vertical coaxial dipole array
for 2 meters made of alternating lengths of (trimmed) aluminum and
fiberglass poles. Maybe the phasing harness could be hidden inside.

34986. Shielded 300 Ohm Twinlead

Yahoo group: ham-antennas (2014)
Date: 2014-12-17 04:17:22 UTC
From: Joe
Topic: 34986 Message: 34986
Attachments: 2 described; binary payloads are missing from this source WARC

I had some of this back in the 70's, It was a larger than usual 300 ohm twin lead for VHF / UHF Television use. Because the typical pair of wires were also surrounded by a foil shield. Thus making it able to run anywhere just like a coax run. I found some online and it is described as such,,

100 feet of BELDEN "CITY COLOR" SHIELDED TWIN LEAD TV WIRE. Two 26 AWG 7x34 stranded copper-covered steel conductors with Beldfoil shield. Recommended for television VHF-UHF-FM use in high interference metro areas. 5 lbs sh.
$10.00 each

In trying to get more details about this stuff again, I contacted BELDEN, and even talked to a tech rep that says they have worked for BELDEN since the 60's and BELDEN has never made such a product. I told her that I used it in the 70's and even gave her the surplus site that is selling it, and she insists still that BELDEN never made anything like this.

I found a patent for something like it. but to me the loss chart seems all messed up and backwards.

The losses seem crazy HIGH for what should be the least lossy configuration.

BUT..... Does anyone have any real data on this stuff? Here is the patent.

The patent was assigned to the "BELDEN manufacturing Company,"
Chicago. I think you know more about it than that "customer service
engineer."

That chart is crazy but, if I'm reading it correctly, the first number in the vertical axis is the % of signal remaining (as it says) and the second number, in the parentheses, is the dB loss per 100ft as a standard attenuation chart is, just reversed as you mentioned.

Hi All,

interesting info on shielded tween 300 ohm TV line. In the second alf of 50s, when in Italy TV started up, we were using tween 300 ohm wire, as it had lower attenuation versus coax cables and was cheaper. On sea side areas this type of fedd line was increasing attenuation due to salt deposit on it. My father, previously I1SWX, was cutting oval or dound holes along the external length of cable to reduce salt attenuation.
Later some ables manufacturers produced a 300 ohm line with a thick foam type of insulation to reduce salt effect. Maybe the copper screen was applied to reduce interferences and salt deposit problem.

There is always something to learn from the past.

Lookup IBM twinax. It is a type of shielded twin conductor with screen.

It's been around for 30 plus years. There are connectors for it. I
don't know its impedance.

Cheers,
Will,

That's funny. I bought a roll of new old stock Belden cable a year or so ago that was labeled with a variation of a very common Belden product number. In the process of trying to get specs on it I called Belden and talked to a woman tech rep that said she had worked there since the 60's and gave me the same sort of story about the cable I was asking about. Apparently, they made a lot of different cables that they never really made.

Everybody needs a hobby, I guess that's hers.

Be cautious when using the older TV/VHF.300 ohm twin lead. First of all, it was usually very light wire (26AWG and smaller) and was designed to be held to TV masts, or whatever, with stand off insulators. Any kind of slack in the twin lead, would result in whipping in the wind, and would break the wire inside the insulation.

It was designed to carry microvolts, NOT the higher wattages put out by amateur XCVRS. QRP maybe, but I certainly would never risk my equipment on something so cheap and flimsy.

With that said, 300 ohm window line is readily available, in heavier stranded wire guages, and works fine where a balanced feedline is required.

Merry Christmas, Happy New Year

I ran Legal limit 1500 out on this stuff all the time. with high SWR's too it fed a loop.

And regular you can not run in conduit, run along ductwork, bury even if you wanted to.

This stuff you can.

A few thoughts....

Maybe that graph shows the loss through the shield; i.e., crosstalk to/from external signals. It makes sense that they want to show you that, since the whole point of the cable (and the patent) is the fact that it is shielded, and so the shielding effectiveness is what they would want to highlight.

But the vertical axis scale is puzzling.

One of the inventors has an unfortunate name! (It reminds me of Professor "I. Lirpa" who used to write for Audio Magazine only for their April issues.)

If you take ordinary 300 ohm twinlead and wrap it with a shield, the impedance goes down. To keep the impedance up there, the wires need to be further apart, and/or thinner. Thinner could mean more breakable, and more lossy. That was the first thing I thought of when you mentioned shielded 300 ohm twinlead.

I have heard of Twinax for a very long time. I think most of it is around 100 ohms, let's say 50 to 150 ohms. That seems to be the target range for most data comms.

Is it possible Belden designed and manufactured this cable, but as an OEM and sold it only to a customer who re-packaged it? Or that it sold only overseas? That might explain why Belden thinks they never had such a product.

Andy

I wrote "Maybe that graph shows the loss through the shield".

No, the graph is showing signal transmission (1/loss) for regular signals. Regular flat twinlead has very high loss (bottom of the graph). I think the patent text is saying it is measured in an environment where the twinlead has contaminated water on its surface; hence the very high loss (low transmission) for regular twinlead.

I have a 35 foot mast made of 2" PVC; I used for tie off points two 4 11/16" square electrical covers and punched 2" holes in the center which allowed them to slide over the PVC; I took metal quick links for chain and put through the screw holes for tie down rope; at the top I placed a long sweep 90 with an eye bolt for a hoist rope. Set in the ground and fasten to the eve of the house and tie off at 20 and 30 feet and it serves as a none conductive antenna mast that works for G5RV and OCF dipole as well.

Hi Lots of plans for tape measure antennas on the internet. They have been around for a long time. Many amateurs also use the geared motors from defunct cordless power tools, like drills etc. The motors are geared and have great torque

Good luck.

"Has anyone tried making a multi-band dipole using two steel tape measures?"

Yes, I have seen it done occasionally. But have seen only little about it on the Internet. There is more about tape measure VHF dipoles, which are not the same thing.

I assume by "multi-band" you mean changing the tape lengths to change bands, right?

"Any suggestions or past experiences or pit falls?"

I haven't tried it myself, so this isn't speaking from experience. But you might need to think about the coiled up part of the tape measures. If you put them at the far ends of the dipole, they probably add a little end-loading (capacitive loading), which can be useful. If you put them at the feedpoint ends, then make sure to contact the tape where it comes out of the enclosure, or you might be feeding the legs through an unknown and unstable amount of inductance.

The longest tape measure I have is 30 feet, which ought to be good down to about 30 meters (or somewhat longer if not restricted to the amateur bands). I've seen much longer tapes.

Tape measures use steel, which isn't the best electrical conductor, but it's OK enough. I don't think its magnetic properties make any difference.

Andy

I actually found a DIPOLE like this at a ham fest. It was Military surplus had a type N connector built into the chassis. Measurement written on the back for different freqs. Pull the tape measure out to specified length and booom instant dipole. Unfortunately I didn't buy it. Kick myself every-time I think of it. There are lots of plans out there for making them on the interweb!!

"Has anyone tried making a multi-band dipole using two steel tape measures?"
Yes, I have seen it done occasionally. But have seen only little about it on the Internet. There is more about tape measure VHF dipoles, which are not the same thing.
I assume by "multi-band" you mean changing the tape lengths to change bands, right?

"Any suggestions or past experiences or pit falls?"
I haven't tried it myself, so this isn't speaking from experience. But you might need to think about the coiled up part of the tape measures. If you put them at the far ends of the dipole, they probably add a little end-loading (capacitive loading), which can be useful. If you put them at the feedpoint ends, then make sure to contact the tape where it comes out of the enclosure, or you might be feeding the legs through an unknown and unstable amount of inductance.

Yepp ... i have also seen that page in the net (and i am also as bad as you in remembering where ... grin)

But if you have seen that then you know how it works

A tape measure sliding up and down in a tubing (pulled up with a gearmotor and a rope)

....

If I remember right there was also a similar thing as a military antenna ... pull out the needed length and youre set ... on the tape there were the frequencies printed instead of inches (or cm)

(needs to bee stainless and no paint on the coils so they short circuit the unused length)

RG58 will do fine. Both RG58 and RG8X are 50 ohms impedance. RG8X just has a higher power rating.

Both are nominally 50 ohms impedance. 8X has a larger center conductor,
lower-loss dielectric, and better shielding than 58. Assuming power
handling is not an issue, the biggest difference between using one or the
other is that by making the balun of one and the rest of the feedline of
another you'd need at least one additional coax connector pair (and its
associated issues--corrosion, water ingress, etc., to hook it all up. If
you stuck with *either* 58 or 8X, you could use one continuous length of
coax from the feedpoint to the shack, winding the ugly balun along the way
(usually near the feedpoint).

```
Coax connectors are always problematic and it's worthwhile to minimize
their use. Also, if you don't have either yet, pay a few more dollars for
8X. It's better stuff.

73,

No if you run less than 200 watts. The RG 58 is for low power with high SWR.

Well, if size is the issue on the balun and you do want to run higher power use RG-303 or RG-142. Both about the same size as 58 but with a much higher power rating.

From: wa2lul@...
Topic: 35007 Message: 35015

In theory it will work fine. In practice it could become problematic over time.

Depending upon the dielectric used, over time the center conductor will migrate over time toward the center axis of the balun (unun) changing the characteristic impedance of the cable used.

35016. Simplified UHF antenna test setup...

Yahoo group: ham-antennas (2014)
Date: 2014-12-20 16:48:17 UTC
From: Ray, W4BYG
Topic: 35016 Message: 35016

For a local club project we are going to build a UHF beam and set up a rather simple UHF test range made up (in Ham style manner... cheap), with available assets that we can cobble up.

At the risk of garnering all kinds of "nay saying", I would like to outline my thinking and ask for helpful ideas that would contribute to making the project useful and informative for the club, many of which are fairly inexperienced hams.

Background:
I grew up professionally in the CATV industry and have over 50 years of professional as well as amateur radio antenna experience. I have also over the years, constructed and tested from scratch, high gain broadcast UHF TV slot antennas, as well as numerous other forms of TV broadcast and amateur antennas. In many of those situations I had sophisticated and expensive test equipment to utilize, but no more... That said:

In general:
We would like to build a fair sized UHF (440 MHz) beam for testing... as well as two well matched dipoles for reference.
We do not have a suitable UHF receiver with an AGC that can be defeated, or a converter to bring the test signals down to HF, or a spectrum analyzer.
We do have several UHF FM transceivers which could be used as a fairly stable signal source.
We can accomplish the necessary matching for the antennas.
We are aware of the reflection variations that can occur on a short antenna range and how to minimize some of that.
We are aware of the need to measure and test in the far field zone.
We would like to keep the construction emphasis on the antenna performances and not complex or expensive electronics. We believe this can be done with available sources and a fairly simple detector. I do have a lab quality 75 ohm attenuator which would be the key to our characterizing antenna gain and front to back.

More specifically:
Given that we would use an existing FM transmitter for the source, for detection, we would like to build up a simple, but 75 ohm input matched diode field strength meter.

The receiving system would consist of a 75 ohm dipole mounted on a 12' telescoping light stand. This would be then connected to the 75 ohm attenuator with a short length of RG59, which in turn would be connected to a 75 ohm link coupled 440MHz tuned circuit , feeding the passive 50 micro amp FS meter.

We are aware of the non-linearity for typical diode FS strength meters. However it is our intuition that this can be overcome by sampling a test signal from the transmit dipole to the receiver dipole, with sufficient energy to get a reading in the upper scale of the FS meter.

Given _that_ reading for a reference, we would then energize the beam antenna with the same source, at the same distance and elevation and engage the attenuator sufficient to match the identical meter reading on the FS meter. In theory, that should give a fairly reliable indication of the tested antenna performance, as well as illustrate to the club some of the details and processes in considering antenna performance.

We would appreciate any contribution others may be able to make, which would help insure the project as outlined, is useful and informative for the club.

Any suggestions into building the 440 MHz matching input to the FS meter would be helpful.

We would like to keep the electronics as simple as possible, so as to not get side tracked into distractive complexities.

Anyone else "been there and done that" or have similar experience which would be helpful?

Your attention and useful assistance is appreciated.
Ray, W4BYG

Interesting project, Several comments that might help. In the past decades the West Coast and Central VHF Society conducted antenna gain contests. They used source antennas for reference that were unidirectional, eliminating the possibility of reflections that could inject errors from High gain Tx antennas. Second, if you do not have a non AGC receiver then I would suggest a matched band pass filter to limit unwanted signals again injecting possible errors and a MAR device to provide tuned gain for the detector. Lastly, the ground reflections from even modest gain antennas is a concern. Usually the antennas are stationed a considerable height differences with the source antenna arranged so that no ground reflections are present. In some cases we put the source antenna on top of a two story building or tall wood ladder and the receiving test antenna pointing up and at an angle to the roof line to eliminate as much as possible reflections. In other words, source signal at the dipole and test antenna on the receiving side,

Just some thoughts.

We would like to build a fair sized UHF (440 MHz) beam for testing... as well as two well matched dipoles for reference.
We do not have a suitable UHF receiver with an AGC that can be defeated, or a converter to bring the test signals down to HF, or a spectrum analyzer.
We do have several UHF FM transceivers which could be used as a fairly stable signal source.
We can accomplish the necessary matching for the antennas.
We are aware of the reflection variations that can occur on a short antenna range and how to minimize some of that.

We are aware of the need to measure and test in the far field zone.
We would like to keep the construction emphasis on the antenna performances and not complex or expensive electronics. We believe this can be done with available sources and a fairly simple detector. I do have a lab quality 75 ohm attenuator which would be the key to our characterizing antenna gain and front to back.

More specifically:
Given that we would use an existing FM transmitter for the source, for detection, we would like to build up a simple, but 75 ohm input matched diode field strength meter.

The receiving system would consist of a 75 ohm dipole mounted on a 12' telescoping light stand. This would be then connected to the 75 ohm attenuator with a short length of RG59, which in turn would be connected to a 75 ohm link coupled 440MHz tuned circuit , feeding the passive 50 micro amp FS meter.

We are aware of the non-linearity for typical diode FS strength meters. However it is our intuition that this can be overcome by sampling a test signal from the transmit dipole to the receiver dipole, with sufficient energy to get a reading in the upper scale of the FS meter.

Given that reading for a reference, we would then energize the beam antenna with the same source, at the same distance and elevation and engage the attenuator sufficient to match the identical meter reading on the FS meter. In theory, that should give a fairly reliable indication of the tested antenna performance, as well as illustrate to the club some of the details and processes in considering antenna performance.

We would appreciate any contribution others may be able to make, which would help insure the project as outlined, is useful and informative for the club.

Any suggestions into building the 440 MHz matching input to the FS meter would be helpful.

We would like to keep the electronics as simple as possible, so as to not get side tracked into distractive complexities.

Anyone else "been there and done that" or have similar experience which would be helpful?

Your attention and useful assistance is appreciated.

Many years ago, QST had a Hints n Tips article which suggested that you could nullify ground reflections if you turned both antennas on their sides. Obviously we're talking about VHF and above.

I've used that method to test the vertical takeoff angle of many mobile antennas I've used, even built a hardware cloth ground screen with an antenna mount in the middle to simulate a vehicle roof. Found some interesting behaviors, even told one commercial company about how poorly their shorty dual band antenna's elevation pattern was. They didn't argue, just sent me a "sample" of the next one up, a dual 5/8ths wave guy... no questions asked.

So,I guess it does work.

Subject: Re: [ham-antennas] Simplified UHF antenna test setup...

Interesting project, Several comments that might help. In the past decades the West Coast and Central VHF Society conducted antenna gain contests. They used source antennas for reference that were unidirectional, eliminating the possibility of reflections that could inject errors from High gain Tx antennas. Second, if you do not have a non AGC receiver then I would suggest a matched band pass filter to limit unwanted signals again injecting possible errors and a MAR device to provide tuned gain for the detector. Lastly, the ground reflections from even modest gain antennas is a concern. Usually the antennas are stationed a considerable height differences with the source antenna arranged so that no ground reflections are present. In some cases we put the source antenna on top of a two story building or tall wood ladder and the receiving test antenna pointing up and at an angle to the roof line to eliminate as much as possible reflections. In other words, source signal at the dipole and test antenna on the receiving side,

Just some thoughts.

Mel,
Thank you for your inputs. They are well received. Especially the addition of a bandpass filter to minimize unwanted RF sources. I did not think of that.

I do have a dual cavity surplus F-242/U variable bandpass filter originally made to tune from 134 thru 170 MHz. The 2 cavities are 9.5" long and about 2" across. On 2 meters this filter measures -.5 db thru loss + or - 1.2 MHz and -20 db + or - 5 MHz. I am not able to sweep it on 440 MHz but could possibly peak it into a Bird watt meter and dummy load.

It might be that it would offer some protection operated on it's 3rd harmonic. I wonder if anyone on the list has tried using a cavity filter made for 2 meters, for a BP filter on 440 MHz?

73,

David is correct, when I said I some time use RG-8X as my smaller cable that I keep the winding to a minimum of 6" dia. RG-8X has a foam dielectric and can migrate if wound too tight Most RG-58's have a solid poly dielectric and can be wound to a tighter diameter

I still don’t get the Ugly Balun thing because its not an effective choke.

Information on how to do a good choke is in the reference below and there is even more data to find if one choses to do so. I had RF issues and the Ugly balun did not help me fix the problem. However once I understood how to implement a choke properly I fixed the issue quickly.

So please read the PDF in the link as a starting point and then go from there, the more data you know about how stuff works the better you will be.

Wow that eHam reference is an interesting read but did not find any real quality data presented by the author. However there were references to other articles and those point to making chokes out of cable through a binocular core. So if one reads it all there is clearly stuff there that can point you in a direction to solve your RF issues.

So here is one set of information that is pointed too in the eHam article and another ones that I have provided for everyones reference.
http://www.yccc.org/Articles/W1HIS/CommonModeChokesW1HIS2006Apr06.pdf

Additional references on the internet to review and understand what you need a choke (balun) for.

http://setxac.com/wp-content/uploads/2013/12/Baluns.pdf

http://audiosystemsgroup.com/CoaxChokesPPT.pdf

http://static.dxengineering.com/pdf/Choosing%20the%20Correct%20Balun.pdf

Bottom line there is information to read and allow you to decide on ways to eliminate RF. But make sure you sift thru the information and really understand it as that’s the only way you can make sure you are not misled by myths propagated from the internet. The target is to remove RF (common mode) on the feedline and not distort you antenna pattern and stop unwanted RF from getting into the shack.

"Are you talking balun,or choke ???"

I think we are talking about a choke balun here.

"Baluns are wound around a ferite core. 1 1/2- inches in dia ."

Some are. And some are wound on an air core.

Baluns come in a wide variety of sizes, some smaller, some larger than your 1.5" diameter.

Changing the material or the size doesn't alter its function.

Ugly balun is the term for an air wound choke or balun. Normally this would consist of coax wound around a cylinder of around 3 inches diameter, plastic to avoid interference. Most recommendations are for the coax to be 18 to 20 turns using around 21 feet of coax. The coax can be glued in place or taped in place. Amounts of turns and footage vary but normally fall into these ranges. Easy to build for anyone.

I have not seen much said on the list about maintaining the minimum bending radius when making coils of coax.

Regarding air wound coax baluns, a 3" diameter coil (text below) of RG-58 is considerably smaller than the minimum radius specification of most manufacturers. In time, the center conductor under the bending pressure will migrate towards the shield and lose it's characteristic precision. It is important to keep this in mind in order for the coax to maintain it's specified characteristics.

Belden's 9201 spec calls for 50.8 mm or a 2" minimum bending radius. The makes the minimum coil diameter 4". If subject to outside weather conditions I would add more. Foam dialectic RG-58 type cable is even more critical, as the foam dialectic does not resist the bending forces as well as the polyethylene RG-58U. I would use a minimum of 6"to 8" for foam dialectic cables.

For RG-8 cables the minimum bending spec is a 4" radius for an 8" diameter coil. Again additional allowance should be made for outside service as well as RG-8 foam cables.

Also, keep in mind regular RG cables were not designed for outside service. Serious consideration must be given to getting a cable with an outside rated jacket and protecting the cable ends from water entry and migration.

Water entry itself is not as much of a problem as the corrosive effects from it mixed with atmospheric contaminants. (That may stir the pot a bit).

Ray, W4BYG

If an indoor cable is immersed in water for any length of time (typical of many buried ducts), the plastic jacket absorbs moisture, changing the cable's electrical parameters.

Outdoor cable jackets contain carbon black or other additives that give them ultraviolet resistance.

I'm not aware of pollution and jacket contamination issues, at least at the pollution levels experienced in Europe and North America. (I can't speak for Beijing, etc.)

I have in the past, had professional opportunity of experimenting with injecting RF signals into water solutions for industrial purposes.

I found pure water in itself does little to attenuate RF signals. It is a pretty good dielectric in itself. Salt water or like contaminated water, is a different story. I surmise the real problem with antennas outside with rain water is mixing with the atmospheric salts and over a long term causing corrosion in the cable, more so at the terminations.

I suggest anyone who is interested in the subject, try a rather simple experiment at home with readily available gear. It will be most revealing and will correct a lot of mis-conceptions about "water problems".

Take a 2 meter FM transceiver, 2- 5' or 6' RG58U UHF jumper cables connected together with a simple UHF barrel, an SWR meter and short cable to a dummy load. Also fill a plastic bucket 1/2 full of tap water and set it on a wood or non-conducting table.

First connect the radio, 2 cables (with the bare barrel connector) to the SWR meter/cable and dummy load with everything dry. Key the transmitter and insure you have a very low SWR, indicating the test set up is working well. If your load is good, it should be close to 1 to 1.

Then take the middle of the 2 connected jumper cables (at the bare barrel connector) and submerge this union into the water bucket. Let it soak for a few minutes. In my experience, you will see little if any change in the SWR, indicating little affect of the water on the transmission line.

My conclusion: only after the water mixes with other contaminates over a period of time, does it cause a problem. In the short term it is seldom a problem. This is generally why you can go out on a "field day" get freshly installed antennas/feedlines soaked from a rainstorm and yet continue to operate with little difficulty.

Another example: I run a fairly nice 500 watt HF and 150 watt VHF/UHF mobile station. My loading coils are modified commercial coils and are exposed to rain as I operate. This includes a completely exposed impedance matching coil at the base as well as the spring mount and associated hardware. I can operate in pouring down rain with no observable affects to my antenna systems. From time to time, I do keep an eye out for corrosion and thus keep the connections clean.

Enjoy,
Ray, W4BYG

The "ugly balun" rears its head from time to time. It has its place in the ham world. And no, there is no "problem" with using RG58 to make one. But let me add more on their use.

IMO, the ugly balun is an "in a pinch" solution, or for experimentation, or for when you suspect a problem and are trying to solve it without having a real choke (unun) on hand. Experience has shown me that it is not a great permanent part of a shack if you want to maximize effectiveness, minimize loss and minimize physical size. It's cost VS effectiveness ratio is quite low, not to mention that on HF, it's a bit large when you have enough turns to form enough inductance to do any good. For low power (8X or the like) it's cost is low due to the price per foot of this type of cable being low at .30 to .40 per foot; even cheaper at flea markets or surplus. In a barefoot situation and with this smaller coax which can take a smaller turn radius, then it's fine to do this and won't hurt a thing. But as I said, there are MUCH more effective methods to make common mode chokes or baluns at nearly same price point, although they take a bit more work. A bifilar wound unit on a toroid is MUCH more effective at about the same price point, not to mention much more compact. (I suggest J Sevick W2FMI's book on baluns and ununs as one of the best resources.)

Someone mentioned using RG303 on an ugly balun of you want high power. Well, only if you want a low price VS effectiveness ratio. At $2.50 per foot minimum typically for RG303, it's some pricey stuff to be wasting in a coil that is minimally effective at choking, especially if running high power. 15 turns on a 4" form (about 15' of coax) will cost you about $40, not including connectors. However, this stuff IS the stuff to use on high power toroidal wound ununs and baluns and is my personal preference for such purposes. Super quality, teflon dielectric, silver plated double shield. It's mil grade quality stuff. Another thing to also consider about this stuff is it is amazingly "springy" for its diameter and is challenging to get to stay where you want it to stay.

Balun VS unun definition? Which is which has nothing to do with being on a core or not. Balun is technically just BALanced to UNbalanced. So if you put an ugly balun at the feed point of a dipole with one end soldered directly to the dipole, then is it technically a balun. If it is in line in the coax with connectors on each end, then it is technically an unun with UNbalanced to UNbalanced. They can perform similar functions. This is mostly semantics and we tend to interchange the terms knowing that other hams know what we mean generally. I know those "definers" out there might pick this paragraph apart, but 95% of you know what I mean without getting into the nitty-gritty. If you don't know the difference between the two, it's time to study, as this is a technical hobby.

There are tons of ways to build effective chokes (ununs) and baluns and what one decides to use in the end is decided through experimentation and experience and in the end, personal preference. I have personally settled on the W1JR toroidal design using RG303 popularized by Sevick W2FMI for most 1:1 applications. It will take 5KW and not even sweat, is quite small and VERY effective. Cost of making these is about $25 each using a type 31 Fair-Rite 2631803802 toroid, 3'-4' of RG-303 with 10 turns on the core and 2 connectors. About $5 more if you use N-connectors. A bifilar design can also be used to save money on the coax, but takes insulating the core heavily and taking great care in the winding interspacing and

must be put in a box which offsets the cost saved on the coax. Too much trouble for my taste. I've gotten lazy since starting using the RG303 and find the extra cost well worth it. This is the same design used by Balun Designs and a number of other manufacturers, except those manufacturers put them in a box. Whether you spend the money to put it in a sealed box or not is up to you and depends on where it is installed.

Happy experimenting!

When I said cable jackets absorb water when immersed in water, I was referring to timeframes on the order of days or weeks. Test labs weigh the cable before and after immersion to characterize cable designs and materials.

Underground ducts accumulate water, so cable in them are immersed. Some buried cables may effectively be immersed depending on drainage.

This phenomenon is well known to manufacturers and users of outside fiber optic cable; cable designers compensate for this by putting water blocking compounds inside the cable. Otherwise, absorbed water freezes and breaks the fibers.

I expect water absorbed by plastic cable elements will change the dielectric as well.

Aerial cables shed rain, so their jackets don’t absorb water. That said, if the ends aren’t sealed or if the jacket is torn or punctured, you can get water inside the cable.

Outdoor copper cables use similar jacket compounds.

===

Corrosion can be a factor with metallic connections at the ends but contamination caused by air pollution should not be a problem for a polyethylene jacket, at least in “First World” air pollution environments.

I base these comments on work with an IEEE standards committee for fiber optic communication cables used in power utility applications. In very high voltage environments (usually transmission lines >100 kV), you can get a destructive interaction between jacket contamination and electric fields under certain very specific conditions. So members of the committee have worked a lot with general issue of jacket contamination and I’ve not heard of other problems. These are fiber cables but in most cases with similar jacket materials.

Is there any reason why an RF choke (Ugly Balun) can't have a couple of eyebolts thereby becoming a double purpose unit? It would eliminate one connector and one possible place of feed line problems.

Another reference without data on the choking impedance that you get with an Ugly Balun.

Lots of references on how to make them but not on what it will do for you. That is why I promote winding chokes using 31 mix ferrite per the references I posted on this topic as there is lots of data on how chokes made this way work.

Cheers

I sent out a previous email about K2SQ work on ugly baluns. Please reference the ARRL antenna manual 21st edition , page 26-26 . It has readings taken at a series of frequencies with H-P 41934 vector- impedance meter on 4 and 6 dia plastic pipes as forms.

The thing that jumps out at me with K2SQ's measurements is the bunched up coax works better on the low bands than the neatly wound versions and by a fair bit too.

35047. Re: [ham-antennas] Re: Open Line Feeders.

Yahoo group: ham-antennas (2014)
Date: 2014-12-24 11:27:44 UTC
From: Ag6az
Topic: 34900 Message: 35047

Quick question. I am about to convert my OCF dipole to an 80m horizontal loop. I bought 30' of 450 ohm ladderline that I will replace the 4:1 balun at the feedpoint so somewhat similar to your configuration then to that 4:1 balun at ground level and then run 100' of 1318 cox to my transceiver.

My question is around flatness of the horizontal loop as its feed point will be at the top of a hill and the antenna will run down at a slight angle about 20 degrees to the bottom of the hill and be like a rectangular shape with an endpoint at the bottom of the hill. Will this configuration work. So far the OCF seems to be a decent configuration (receives and transmits signals fairly well) at the top of the hill with the longer leg running downward slightly.

Thanks & Happy Holidays,

Keith

> I use a 400 foot horizontal loop up about 40 feet and fed with 450 ohm ladder line. From the feed point, the ladder line goes to a 4:1 current balun. Out of the balun there's about 6 feet of RG213 to a remote auto tuner. Then about 100 feet of RG213 from the auto tuner to the shack. The remote tuner and balun are strapped to one of the trees which support the loop. Bringing the ladder line all the way to the shack was not an option for me. This solution adds to the cost of the antenna, but its still very inexpensive especially given the versatility it provides. Also, feeline loss is minimized as the tuner is located out at the antenna. Once the tuner finds a match, that 100 foot run of coax sees 50 ohms present at each end.

As a rule the higher the impedance of any line the lower the feedline
loss and the less effect returned power will have on overall antenna
system loss.

Keith,

I'd be less worried about the shape and more worried about the input impedance at the loop. Your 4:1 balun will transfer energy most efficiently when it is attached to a 200 Ω load without much reactance. It cannot be guaranteed without some knowledge of the input impedance of the loop. That impedance can either be modeled or measured. Measured, but you would have to be at the feed point with an analyzer and that's not an accurate representation of the finished configuration with the transmission line (TL) and its effects to the radiation pattern. That leaves measuring at the TL line input and mathematically subtracting it which is equivalent to using an analyzer that can calibrate out the TL, then measuring the antenna with this calibration to reveal the true input impedance with the TL in place. Another way to model without a computer simulation would be to assume the input impedance and use a Smith chart to back out that TL.

Assume 100+j0 at antenna input because it is closer to ground (unless you have that loop up 65' or more). Then add 30' of 450-Ω TL (approx 0.12λ = 43° using my measured value of 0.89 vf for window line). Reveals that the TL input impedance is 182+j383 Ω, a 20:1 VSWR. A most impossible situation for the balun.

Here's how you could make it work better. Don't use 450 Ω line, use 75 Ω line such as coax. If you run that loop on 80m only that line will transform the load impedance down to an impedance of no greater than 100 Ω and the VSWR will never go above 2:1 no matter what TL length you use. If you want multi-band bliss you may have to get creative with that TL length to obtain some harmonically related length that will allow low impedance mismatch across whatever bands will come out of that process. More work than what I'd prefer. If it was me putting that system together, I'd opt for a decoupled SGC-230 tuner at the input to the 450 Ω TL and remote tune it like I currently do for my loop (minus the TL).

Please feel free to ask more questions. I can even send some pictures to help you out.

From: Ken
Topic: 35048 Message: 35051

Good question, here are my thoughts:

Single band antenna with a known impedance (e.g. folded dipole) or a multi band antenna with widely varying impedance (e.g. 80m dipole fed on all bands).

If a known impedance, such a a 300 ohm folded dipole, I would use matching line.

If widely varying impedance, such as a multband unmatched dipole, I would go with open wire (usually higher impedance) because it’s cheaper, less affected by weather, and blows around a lot less in the wind and has less loss.

I am open to other views.

Terry,

Ron is correct, but in addition to that, another property of using higher impedance transmission lines is to transform impedances. With a 50-Ω source and a high Z line one can easily transform the input impedance of an antenna back down to something close to 50-Ω and all you need is a Smith Chart (and some knowledge of how to do so). Check out the Smith Chart section of any ARRL Antenna Book. Also, read up on mismatch loss, you can then understand why it may be necessary to eliminate mismatch or knowing when it won't matter.

Strike "radiation pattern" and insert "input impedance". (While radiation pattern is affected by the presence of a TL, we are most concerned about the antenna input Z at this point).

Have used RS 300ohm twinlead for years to feed an ~ 88' doublet for multilband use since it was once fairly cheap and readily available. It also seems to withstand the weather and hot Texas summers quite well. The present installation is 6 years old. With the demise of the company, suppose will need to use something else in the future. I don't find that the length of the feedline or the antenna is critical, the balun is on the back of the MN-4C tuner. Suspect that the feedline impedance isn't particularly important if the length is less than 100' and it is being used with a high SWR on it anyway. The performance has always been great, am usually working with 0.5-5W output. Certainly running more than 100W would not work with this feedline.

Am presently building a loop and will use the same feedline, with a 1:1 current balun at the tuner.

If only wanted one band, would likely use a resonant dipole fed with coax, but wanting all bands 40-10, non-resonant antenna fed with low-loss feedline is my only choice.

But I think there was a limit on how high you can go, because if I
remember correctly the line looses it's feedline characteristics, and
it's self shielding properties. It starts to behave like two seperate
end fed long wires.

There is a reason the old timers stopped at about 600 Ohms,

Curt,

I always considered an open wire fed dipole to be a great multi band antenna, UNTIL MY LAST ONE. I had up a 160m inverted ver (50’ at the apex). Fed with open wire.

It was VERY difficult to load on 160 and 80m, although it loaded up fine above those bands. I believe the problem was the impedance transformation from a very low impedance to a very high one at the shack end. I replaced the open wire with coax and added an 80m section to the antenna (fan dipole style) and it loads easily on both 160 and 80.

It may be a tiny bit directional, in in the direction on the downward side. But it will be such a slight directivity, you would be very hard to notice. matching the feeder line to an antenna depends on what impedance shows at the shack end the fed line, the if its high or low you use the right balun to bring impedance to 50 to 75 ohm to match transceiver.
  I hope this answers your question. jeff

From: Mel Farrer
Topic: 35048 Message: 35060

I have always been an advocate of open line 300 or 600 ohm lines on large OCF and double extended Zepp antennas. Main reason is that the impedance is always a complex value when considering multi band operation. Example my double extended Zepp for 160 is >350 long fed with 600 ohm line. The length set to offset the reactance on 160. Turns out that it works on all bands, some with a good 50 ohm match some need a little tweek, hi.

Of course you need the place to hang it. Merry Christmas.
Mel, K6KBE

  But I think there was a limit on how high you can go, because if I remember correctly the line looses it's feedline characteristics, and it's self shielding properties. It starts to behave like two seperate end fed long wires.

There is a reason the old timers stopped at about 600 Ohms,

Terry Cheek kk4ixe@...:

When choosing a flat line what criteria do you use when deciding on 300,
450 or 600 ohm impedance to use as feed line?

As a rule the higher the impedance of any line the lower the feedline
loss and the less effect returned power will have on overall antenna
system loss.

I put the EZNEC antenna file for my 160 meter EDZ antenna with the ladder line matching section. Please note this approach is to match out the reactance of the antenna and convert the high impedance down to 50 ohms. Not difficult just laborious. No antenna tuner needed for the primary design frequency.....

The "tape measure" style dipole was manufactured by both Collins Radio and Hy-Gain during the 1960's. The Collins antenna was sold primarily to the military while the Hy-Gain dipole was offered commercially to the amateur market as well.

Yes, I have seen it done occasionally. But have seen only little about it on the Internet. There is more about tape measure VHF dipoles, which are not the same thing.
I assume by "multi-band" you mean changing the tape lengths to change bands, right?

"Any suggestions or past experiences or pit falls?"
I haven't tried it myself, so this isn't speaking from experience. But you might need to think about the coiled up part of the tape measures. If you put them at the far ends of the dipole, they probably add a little end-loading (capacitive loading), which can be useful. If you put them at the feedpoint ends, then make sure to contact the tape where it comes out of the enclosure, or you might be feeding the legs through an unknown and unstable amount of inductance.
The longest tape measure I have is 30 feet, which ought to be good down to about 30 meters (or somewhat longer if not restricted to the amateur bands). I've seen much longer tapes.
Tape measures use steel, which isn't the best electrical conductor, but it's OK enough. I don't think its magnetic properties make any difference.
Andy

35068. Matching antennas without a tuner

Yahoo group: ham-antennas (2014)
Date: 2014-12-27 22:01:39 UTC
From: farrerfolks@...
Topic: 35068 Message: 35068

I have always approached an antenna design from the point of view of not requiring a tuner on the design frequency. Yes, a tuner makes it easy, but it has more loss, requires constant changing or updates, etc. I prefer to design it OUT. Yes, away from the design frequency a tuner is nice. So, I have taken my double extended Zepp antenna for 160 meters as an example and wrote up a word document on the approach I used, and you can use on any simple antenna design. In this case a balanced fed antenna. I will put the document in my K6KBE EZNEC file section. Cheers,

Mel

35072. Mystery antenna and tower that was never made

Yahoo group: ham-antennas (2014)
Date: 2014-12-28 20:02:30 UTC
From: Kathy Bookmiller
Topic: 35072 Message: 35072

We are trying to identify just what this yagi is of a recent SK.
Took a few pictures of it the other day and have this description:

We are still trying to help find someone who is interested in Fred's (W2UB) tower and beam. So far we haven't been able to determine the make and model of the beam. Please check out the attached pictures and let me know if you recognize it. There appear to be some sort of "V" shaped rods connecting each side of the 'second' element to the corresponding side of the 'fourth' element.

It should become available in the spring, along with the tower. Anyone recognize just what it is?

As a bonus question, anyone know who made the tower? I know what it is and it supposedly doesn't exist as the company claims they never made crankup towers, but they did as their name is on the crank/pulley assembly. (the SK had two of these towers, but one came down in high winds last spring and we've already cut it up and removed it for scrap)

35076. For Sale Parts "Kit" for a CobWebb Antenna

Yahoo group: ham-antennas (2014)
Date: 2014-12-30 18:55:07 UTC
From: ingerassociates@...
Topic: 35076 Message: 35076

I have gathered together all the necessary parts to construct a compact CobWebb multiband dipole antenna. If you aren't familiar with these great performing small antennas, a quick web search will provide you with lots of info. I have plenty of pdf's and website references that will give you the necessary info to construct this antenna. The best place to start is G3TXQ's website (http://www.karinya.net/g3txq/cobweb/).

My kit" consists of:
Four 8 ft. long 1/2" diameter fiberglass poles from Max-Gain Systems
One manufactured center hub
Two FT-240-61 toroids and RG-400 coax for constructing G3TXQ's 1:4 balun. This will allow legal limit power. Smaller toroids can be used for lower power systems.
One 4"x4' NEMA plastic box for the balun and terminating point for the dipole wires

You will need to supply about 100 ft. of 16- or 18-ga wire. This is enough for each of the dipole wires for 20/17/15/12/10-meters. Some zip ties and other bits and pieces available from any hardware store is all that you will need.

Everything is brand new and unused; I think I will go the hexbeam direction instead (unless my wife threatens divorce...or worse).

I will sell this for $60 which is 50% of what I paid for the items, plus shipping. It will be shipped in two boxes. The fiberglass poles can go by UPS but there is some added cost due to the length. If you are interested I can calculate the UPS costs to your QTH.

Pleas contact me off list at ingerassociates@cox.net.
